BOOK REVIEWS

Manuscripts and editorial correspondence relating to the regular quarterly issues of the REVIEW should be addressed to Bernard F. Haley, Managing Editor of THE AMERICAN ECONOMIC REVIEW, Stanford University, Stanford, California.

OTHER DEPARTMENTS

HAROLD ADAMS INNIS

Fifty-fourth President of the American Economic Association, 1952

Harold A. Innis was born at Otterville, Ontario, Canada, on November 5, 1894. He died at Toronto on November 8, 1952. After receiving his B.A. degree at McMaster University in 1916 and his M.A. in 1918, he went to the University of Chicago to continue his graduate work and received his Ph.D. degree there in 1920. Glasgow University awarded him an honorary LL.D. in 1948.

In 1920, Dr. Innis became lecturer of political economy at the University of Toronto, was advanced to an assistant professorship in 1924, to an associate professorship in 1929, and to a full professorship in 1936. He was appointed head of the department in 1937 and dean of the School of Graduate Studies in 1947. These latter positions he held until his death.

Professor Innis was a fellow of the Royal Society of Canada and corresponding member of the Royal Economic Society. He served as representative of the American Economic Association to the Social Science Research Council, 1947-52.

An account of Harold Innis' life and works may be found in the papers presented at the Memorial Session of the December, 1952, meetings and published in the March, 1953, issue of the *American Economic Review.*

Number 54 of a series of photographs of past presidents of the Association.

VOLUME XLIII MARCH, 1953 NUMBER ONE

HAROLD ADAMS INNIS*

1894-1952

I

Canadian social scientists unanimously approved and rejoiced when this Association elected Harold Adams Innis as its president: they recognized alike the wisdom and the generosity of this action. Your election of the alien Innis was a finer tribute than my words can frame. It is my duty, however, to attempt to express the affection we had for him, and the intellectual and moral debt we owe to him, and to recall to mind some qualities of the man we honour in order that we may, to borrow words from an address in memory of Wesley Clair Mitchell delivered by Dr. Willits, "acquire increased strength and discernment for ourselves and others by contemplating the qualities which made him unique."

Harold Adams Innis was born on November 5, 1894, near the village of Otterville in southwestern Ontario. His was the rigorous educational experience of the son of the farm: chores, a walk to the station, a twenty-mile train journey to attend Woodstock Collegiate Institute, the return journey and again the chores. No wonder that he chose to quote these words of Leslie Stephen when he addressed the Conference of Commonwealth Universities in Oxford in 1948: "Receptivity of information which is cultivated and rewarded in schools and also in universities is a totally different thing from the education, sometimes conferred even by adverse circumstances, which trains a man to seize opportunities either of learning or of advancement." No wonder too that in the Report of the Manitoba Royal Commission on Adult Education he warned against evils of the examination system by which students are selected from the schools for admission to universities. "The results," he said, "are evident in the success of students in large

* The succeeding papers were presented at the memorial session in honor of the late President Innis held at the Sixty-fifth Annual Meeting of the American Economic Association, December 28, 1952.

cities and of middle-class parents. Uniformity of examination systems over wide areas involves wholesale discrimination against districts which cannot attract the best teachers or command the best equipment." But it was not the injustice to individuals of such discrimination so much as the national loss that appalled him. "Any community," he wrote, "has only a limited number capable of sustained mental effort. . . . A democratic society can thrive only by the persistent search for its greatest asset and by constant efforts to conserve, to encourage, to train, and to extend it. . . . Universities must strive to enlist most active energetic minds to train most active energetic minds."

Harold Innis graduated from McMaster University as a Bachelor of Arts in 1916 and immediately enlisted as a signaller in the Fourth Battery of the Canadian Field Artillery. He served overseas and was wounded. He did not speak of these experiences but they were not forgotten. Years later, in an address to students on Armistice Day, 1933, he said: "It has not been long since most of us have been awakened by nightmares of intense shell-fire, and even now the military bands played with such enthusiasm by young men are intolerable, and Armistice Day celebrations are emotionally impossible." One suspects that the cruelty of army life was an important influence in solidifying his belief that the individual must be protected from the institution. Returning to Canada, still partially disabled, he was determined to continue his studies and determined that his field should be economics. He won his M.A. degree at McMaster in 1918, and went on to Chicago for his Ph.D. He was very fortunate in his choice of a graduate school for this was a great period in the history of a great university. Our chairman, Professor Chester Wright, was primarily responsible for his direction but Clark, Knight, Millis, Moulton and Viner were among the professors who stimulated, encouraged, and influenced him. Perhaps equally important were the students with whom he worked: of these I know he would have paid tribute to James Angell, Morris Copeland, Carter Goodrich, Walter Smith, Miss Cleona Lewis and Miss Helen Wright. His doctoral thesis, *A History of the Canadian Pacific Railway,* was published in 1923.

Harold Innis was appointed to the staff of the University of Toronto in 1920 as a lecturer in the department of political economy. In that department he spent his whole professional career. In 1937 he became the fifth head of the department in succession to W. J. Ashley, James Mavor, R. M. MacIver and E. J. Urwick. He was, it will be noticed, the first Canadian to hold that position. It is a department in which economic theory and economic history, political theory and government, sociology, and commerce are all included. The atmosphere of the department makes for breadth; the mere specialist would find it un-

congenial. For Harold Innis this was the right kind of department in which to grow; for the department Harold Innis was pre-eminently the right kind of head. The economic historian became the social scientist, the social philosopher, the humanist. The strong historical tradition begun by W. J. Ashley was renewed and strengthened; but he was alert to the necessity of progress along theoretical lines too. It was this same breadth of scholarly vision that made appropriate his appointment in 1947 as dean of the newly reorganized School of Graduate Studies, and in 1951 as chairman of a President's Committee on the Humanities. This task unfortunately was unfinished.

Harold Innis gave much thought to the rôle of the University and the dangers that beset it. Its rôle, he believed, was crucial for western civilization; anything that endangered it threatened that civilization. He closed an address to a wartime Convocation at the University of New Brunswick, after having been admitted to the degree of Doctor of Laws, *honoris causa,* with these words:

> As recent graduates, we dedicate ourselves afresh to the maintenance of a tradition without which western culture disappears. We pay tribute to the memory of those who fell in the last war, and of those who have fallen in this war, by the ceremonies in which we have participated. These ceremonies peculiar to an institution which has played the leading role in the flowering of western culture remind us of the obligation of maintaining traditions concerned with the search for truth for which men have laid down and have been asked to lay down their lives.

At a similar ceremony at McMaster University he said: "You and I have become today members of a community which in a very real sense is the life of western civilization." The dangers came from those who feared free inquiry, from the Church, the State, and from Business. "Business and political exploitation of universities by bribes," he said in the address at McMaster, "reflects a complete inability to understand that universities honour donors and not donors universities. The impression that universities can be bought and sold, held by business men and fostered by university administrators trained in playing for the highest bid, is a reflection of the deterioration of western civilization. To buy universities is to destroy them and with them the civilization for which they stand." There were, however, more subtle dangers within, especially related to the advance of science and the mechanization of knowledge. In a paper entitled "A Plea for Time" he wrote about the trend in universities to add courses because people like to do them, because they will be useful to people after they graduate, because members of the staff like to give them, and because an additional course means a larger department and a larger budget.

> These tendencies reflect a concern with information. They are supported by the text-book industry and other industries which might be described as information industries. Information is provided in vast quantities in libraries, encyclopaedias, and books. It is disseminated in universities by the new media of communication including moving pictures, loud speakers, with radio and television in the offing. Staff and students alike are tested in their ability to disseminate and receive information.

Later in the same paper he said:

> The blight of lying and subterfuge in the interest of budgets has fallen over universities, and pleas are made on the grounds that universities are valuable because they keep the country safe from socialism, they help the farmers and industry, they help in measures of defence. Now of course they do no such thing and when such topics are mentioned you and I are able to detect the odour of dead fish. Culture is not concerned with these questions. It is designed to train the individual to decide how much information he needs and how little he needs, to give him a sense of balance and proportion, and to protect him from the fanatic.

Veblen in *The Higher Learning in America* was not more scathing; but Innis was perhaps more hopeful, and more helpful. For these are only his words. We who worked with him in the University can testify to deeds and to a powerful influence for good in the councils of the University, and above all in personal discussion.

Harold Innis was a scholar of tremendous industry. Not content with books and documents he travelled all over the Dominion to get the feel of that economic life about which he wrote. Typical of such activity was his toilsome and dangerous journey down the MacKenzie River. I still remember his pleasure when he heard himself described as the best deck-hand in the North. His publications are so many that the preparation of a complete bibliography will require considerable work. The land marks were: *The History of the Canadian Pacific Railway* (1923), *The Fur Trade in Canada* (1930), *Settlement and the Mining Frontier* (1936), *The Cod Fisheries* (1940), and *Empire and Communications* (1950). Two volumes of collected papers from which many of the quotations in this tribute have come should be noted: *Political Economy and the Modern State* (1946) and *The Bias of Communication* (1951). A final volume of essays, *Changing Concepts of Time* (1953) published a few days after his death is a monument to his courage. He had revised the papers and read the proofs in spite of his illness. So had he driven himself all his life. Though his industry was tremendous, hard work never dulled his imagination. He knew the facts, and he recited them in his writings: but his was not that antiquarianism, that "useless accumulation of useful facts," which he

denounced. The contemplation of the facts led to penetrating insight Dr. R. A. MacKay in a tribute in the *Ottawa Citizen* put it this wa

> Of a reflective, imaginative, and almost intuitive cast of mind, he had a singular capacity for seeing significant relationships between the material environment and ideas, and between facts themselves, which often escaped the more pedestrian scholar. . . . At times his original mind leaped great chasms to conclusions which more timid or less imaginative minds could not follow.

Great and distinguished as was his contribution to scholarsh through his own writing, perhaps even greater was his contributi through the development, stimulus, encouragement, support, and occasion chastening, of his students, his colleagues in the Universi of Toronto, and his fellow workers in Canada and the United State fellow workers not just in economic history but in all the social scienc and in the humanities too. George Ferguson writing in the *Montre Star* did not exaggerate when he spoke of the "enormous influence" exercized and when he went on to say:

> The man had power he did not know he had. The social scientists of Canada—and many men besides—were largely Innis men. Scarcely one of them but had not come under his purging, beneficent authority. He drove their minds relentlessly into new and deeper categories of thought. He praised them and scourged them for their own good, and only the incompetents and the blind resented what he did.

He had early realized the importance of communication among tl social scientists of Canada, of ending the feuds and competition of tl past and of beginning a period of friendly cooperation. One thi needed was a Journal. In 1928 he persuaded the University of Toron to begin to publish at irregular intervals *Contributions to Canadi Economics*. He played an important part in the revival in 1929 of tl Canadian Political Science Association and a crucial part in 1934 the founding of the *Canadian Journal of Economics and Politic Science*, to replace *Contributions* and the *Proceedings* of the Associ tion, and to extend the possibility of publication. The Canadian Soci Science Research Council was largely his creation: he was a memb of its executive board in its formative years and its chairman from 194 to 1948. His part in the establishment of a parallel council for tl humanities was important and crucial. In all these organizations strove to ensure that they would give support to the individual schol following his own line, and not distort the free growth of scholarsh by bribing men to conform to the plans of others.

On three occasions Harold Innis accepted appointments as Roy Commissioner: the Nova Scotia Royal Commission of Economic I

quiry (1934), the Manitoba Royal Commission on Adult Education (1946), and the Dominion Royal Commission on Transportation (1948-50). While his direct participation in the making of public policy was limited, he was deeply concerned and not uninfluential. But certain important attitudes should be noted. First, there was the duty of the scholar to the University to maintain his integrity, his independence, his continued questioning. He was suspicious of scholars who played too large a part in public affairs. Second, his concern was not with the present—"real, insistent and complex"—not with months and years but with generations. One of the most dangerous trends of the time was that "foreshortening of practical prevision," which was illustrated by the readiness to accept Keynes's quip, "In the long run we are all dead." Third, there was the danger of a growing readiness to grasp at "solutions." "As an economist," he once said, "I am constantly faced with the extraordinary difficulty and complexity of the social sciences and constantly forced to admit defeat. If an economist becomes certain of the solution of any problem he can be equally certain that his solution is wrong." Finally, what particularly appalled him was readiness to find solutions in planning and regimentation. There is a speech he made before the Board of Evangelism and Social Service of the United Church of Canada which contains much that I would like to quote; from it I select these passages:

> The discussion of questions which affect people's lives must be carried on with great circumspection. I have had occasion recently to come in contact with two professions, the nursing and medical profession, and to be impressed again with the assumption that a long period of intensive training is essential to the preparation of individuals who are to be concerned throughout their careers with the handling of problems affecting people's lives. I have been appalled on the other hand and by comparison with the cavalier fashion in which great numbers of people discuss the problems of managing people's lives with almost no intensive training. Dale Carnegie's *How to Make Friends and Influence People* is a symptom of a widespread interest in the technique of pushing people around. In universities the rise of the social sciences and in particular the emphasis on business subjects, personnel management, industrial relations, social work, applied anthropology and so on point to the danger of forgetting that no one can undertake the task of pushing people around without a long period of intensive discipline and training, though in fairness it should be said there is a widespread appreciation of this danger.

Later in the same speech he said:

> I have indicated the physician and the nurse as types of special disciplines that are necessary, people who respect the individual and know when to leave him alone, but first of all they know their subject thoroughly. But

> skill and discipline are of little value unless the practitioners of good works are selected for their integrity and the high quality of their characters.

Harold Innis was the recipient of many honours, which he bor modestly, even apologetically. He was elected a Fellow of the Roya Society of Canada in 1934 and became president of that Society i 1946. He was elected president of the Canadian Political Scienc Association in 1937. In 1942 he was elected president of the Economi History Association, succeeding Edwin F. Gay, the *doyen* of America economic history. In 1944 he was awarded the Tyrrell Medal of th Royal Society of Canada. In 1949 he was appointed Beit Lecturer i Oxford University and Stamp Memorial Lecturer in the Universit of London. Honorary degrees were conferred on him by the Univer sities of Glasgow, Laval, McMaster, Manitoba, and New Brunswick

I should not leave with you this picture of the austere scholar with out a word about the man. Professor Donald Creighton, an intimat friend over many years, described him in a broadcast of the Canadia Broadcasting Corporation:

> The tall, slight figure, the unruly plume of hair, the genially sardonic smile were well known and well loved throughout Canada. To a whole host of admirers and disciples, he will be remembered not as a row of books, only partly personified, but as the most companionable and interesting of men. Nobody could relax more completely and wholeheartedly than this austere and tireless scholar: nobody ever got more interest and amusement out of a few minutes' chat, or an hour's gossipy conversation, or a long evening's talk ranging cheerfully and haphazardly over a great variety of books, and people, and places. He will be pleasantly remembered as he was on these occasions—sitting usually in a straight-backed uncushioned chair, tilting himself back occasionally and occasionally emphasizing a point in the argument with an awkward but expressive gesture of his long, strong hand. His study became a kind of clearing-house for the academic gossip of a large part of the English-speaking world. He had a great fund of stories, for men told their best anecdotes in his presence, and his own humour was rich, and generous, yet delightfully astringent. He was master of jocular irony and sly understatement. He could be sardonically funny at the expense of pretence, and pomposity, and complacence, particularly when they were cushioned in fatty deposits of wealth or position. He was good company—urbane, entertaining, stimulating.

Mr. George Ferguson, another of his intimates, described "the relaxe genial man whose entry into a room intensified the quality and gaiet of the day. He laughed easily, deep laughs from his heart, and he love other men's humor. His own was rich and sardonic. The help he ga

others he gave without measure or thought of return. His sense of personal dignity was not largely developed, though his deep sense of the integrity of freedom was unquestionable." To these I add my testimony: This great scholar was a modest man with a great gift for friendship. Hard as he worked he never seemed rushed but he always had time to talk with his friends. He was a good listener; when he spoke his words were few but pointed. His handwritten notes of congratulations were treasured by those who received them. It was in an atmosphere of friendship that his great moral and scholarly influence was unobtrusively exercised.

V. W. Bladen

University of Toronto

II

Arthur H. Cole observed recently that economic historians who achieve the presidency of this Association are much more than economic historians. Harold Innis like Edwin Gay was a man of wide interests and stimulating mind. His influence extends far beyond his writings and it would be unjust to him to stop with his written words. The following observations are based quite as much on conversations with him as on his published work; it is hoped that in this way some of the virtues of the oral tradition which he esteemed so highly may be preserved even though the written form win in the end.

It was perhaps inevitable that from the beginning Dr. Innis should attack the problems of history on a broad front. Writing as a Canadian economic historian he was constantly faced with the fact that in Canadian development the strategic decisions, the shaping influences, had always to be sought outside the country's political boundaries. Study of an economy so vulnerable to external forces made the writing of a national economic history out of the question. And there is the fact, too, that this history is marked by the absence of any break with European traditions, of alienation or turning back on the old world. Much of Canada's economic history is simply an extension of European economic history; only over the past century has it become an extension of the economic history of the United States.

Study of this "international" economy of Canada led him early in his work to the conclusion that ranking in importance and closely associated with economic influences and pulls were cultural influences and pulls, and his interest in cultural relations is apparent long before he turned from "staples" to "communications." In the shift of interest from pre-occupation with the trade routes of commerce to the trade routes of culture, from the exchange of staple commodities to the ex-

change of ideas or information, there is no suggestion of a break or lo of continuity in thought or interests.

Another element of continuity in his work is apparent in his set values, or more loosely, his likes and dislikes. There stands out in eve phase of his activity—writings, lectures, departmental administration- an intense individualism, an almost obsessive preoccupation with t virtues of unrestrained exchange (whether reference be to commoditi or ideas)—the spirit of free enquiry, the give-and-take of spontaneo discussion, faith in the creative powers of the individual left alor There is the suggestion of "ideal type" method in his writings on t aggressive commercialism of the New England fisheries and trade the North Atlantic and in his frequent references to the oral tradition Greece.

This attitude may be illustrated from his writings and is perhaps mc clearly brought out in his dislike, even contempt, for the written tra tion, his fear of the written word as frozen, final; throughout there apparent a constant struggle to break down this finality and to weak or destroy the inherent tendency to monopoly of communications whi he firmly believed to be a fatal defect of the written form. This hel to account for the absence of final or complete statement in his public tions, his impatience with orderly presentation or the continuous d velopment of narrative, his technique of juxtaposing unlike elements a means of seeking insights into process. He searched, probed, soug elements of strength and weakness, but nowhere gives any indicati of interest in constructing a system, or a theory of historical chang

Along with this individualism went an equally intense realism. The is no lack of awareness of the weakness of small units, of maritime are faced with the power of continents, or of the limitations of the city stat In the main his work centers on the history of bureaucracies, admini trative units in control of large territories, in short, empires in whi centralized control of communications has been the rule rather than t exception. How to reconcile his set of values with the survival needs large power structures was for him one of the crucial questions to asked of history. He first raised this question, I think, in his study the Northwest Company, a transcontinental fur trade organizatio which in its failure to achieve a balance necessary to reconciliation the demands of enterprising individuals in the trade with the stabili requirements of the organization, bowed out to a power more successf in its handling of the problem. The same question is writ large in h reflections on the values of Greece in the world of Rome, and althou little of this has appeared in print, in his frequent references to t amazing survival powers of the Byzantine Empire. He raises the que

tion again in his remarks on the United States in his recently published volume of essays, *Changing Concepts of Time,* whose subtitle might well have been "Washington, the Third Rome?"

There is no suggestion that the problems he was concerned with are new problems or again, that his use of communications studies as a means of understanding different cultures and economies is uncommon among social scientists. What he *did* do in his examination of the communications networks of empires, the means or mechanisms by which ideas, information, orders, commands, are given or exchanged, was to give the whole a strongly historical twist or bent and in doing so to greatly enlarge the area of enquiry both in space and in time.

As I have indicated, there is a close and logical connection between his recent work on communications and his earlier studies in Canadian economic history. How he came to shift from concern with trade and staples to the stability conditions of empires is one of the few questions relating to his work in which a simple explanation seems to be adequate. As he put it in conversation, he set out to adapt the work of J. M. Clark and Thorstein Veblen to his own field of historical investigation—technology and the price system—unused capacity as a factor in economic history—and developed in the process tools which he put to highly profitable use. He employed these with great effect in his studies of the fisheries, the fur and timber trades, canal and railway developments, the wheat economy of the prairies and the early industrialism of central Canada. It was when he turned to the new and more complex industrialism of hydro-electric power, pulp and paper, and new metals, that he felt the need of broadening his concepts, sharpening the old tools and devising new ones.

More immediately, it was in his study of the pulp and paper industry that he was driven to consider that primary medium of communication, the newspaper, and its place in economic development. A reading of his articles on the newsprint industry and the press will bring out, I think, the growing recognition on his part that in *all* his work *communications* had been, in fact, the unifying theme and that to continue in this direction he had no recourse but to turn to the study of history of media of communications, their timing and their impact. In short, study of communications seemed to be the most effective approach to an understanding of the larger environment of economic activity, and although he seemed to be moving a long way from matters normally the concern of economic historians, the economic element was never overlooked or forgotten.

It was not much more than a decade ago that he embarked on this new venture, and his work over this period bears witness to his prodigious labors and his almost frightening self-sacrifice. When I ex-

pressed misgivings as to the risks involved in this move into the large and complex area of communication systems which extend into every avenue of human experience, an area, moreover, in which experts of every stripe and color had established strong vested interests, his reply was that in spite of the imperfections which were certain to be present in this working in strange territories, experts might put right what was wrong, and much more important, that it was high time that localized monopolies of knowledge held by antiquarians and others were broken down.

It was perhaps inevitable that there should be misunderstandings and occasionally hostility, but there was cooperation too and a genuine and growing interest on the part of those who could help. And there were sufficient indications of awakening interest in alien quarters to make him reasonably certain, before his work was cut short, that the venture had not been in vain. I saw much of his correspondence over this past summer and can attest to this change, but I cannot help feeling that the years of the early 1940's must have been for him very lonely years.

In his later work, technology and pricing factors cease to provide the backbone of his enquiries and come to serve more and more as starting points. Major changes over history in the technology of communications are themselves culturally conditioned, and Innis' writings on law, religion and politics attest to the absence of the technological determinism with which he is sometimes charged; he was too aware of the close interrelations of technology with institutions and physical environment to fall into this trap. In his analysis of the determinants of change in communications systems and the consequences of such change in specific cases there was one test of performance which he invariably applied, namely, the degree or extent to which these changes strengthened the element of monopoly in communications networks, or conversely, weekened or destroyed obstacles to the free exchange of ideas or information. In his reflections on twentieth century industrialization of the means of communication in the United States, the arch-criminals are identified as vast monopolies of knowledge which, as he put it, threaten "a continuous, systematic, ruthless destruction of elements of permanence essential to cultural activity" (*Changing Concepts of Time,* p. 15).

The villain of the piece is bias in communications which in present-day North American culture is manifest in its fatal obsession with things of the present, its one-sided concern with the logistics of territorial control (whether this be geographic area or markets), its reliance on political action for the solution of all ills. Changes in communication, both in form and content, have led to a neglect of problems of duration, stability, a neglect which has destroyed empires in the past. In his own words:

Shifts in new media of communication have been characterized by profound disturbances, and the shift to radio has been no exception. An emphasis on continuity and time, in contrast with an emphasis on space, demands a concern with bureaucracy, planning, and collectivism. Without experience in meeting these demands, and appeal is made to organized force as an instrument of continuity. . . . Lack of experience with problems of continuity and empire threatens the Western world with uncertainty and war" (*The Bias of Communication*, pp. 188-89).

The tragedy of Innis is the abrupt halt to work in process by one at the height of his powers. The loss is the greater because of the author's attitude toward the written tradition, an attitude which makes prospects for completion of his edifice of thought by others exceedingly dim. Those familiar with his writings need no introduction to his method—the amassing, sifting of evidence, the intuitive flash with connection between fact and conclusion seldom clear, finally the process of working back, establishing the connection so that others may see, communicating more effectively with those who care to read. The brevity of this phase of increasing intelligibility may lessen the immediate impact of his thought and writings, but I doubt that it will reduce the force of impact in the long run, however long run be defined.

There is one aspect of his later thought which should be stressed, and that is the tendency to turn more directly to consideration of the interrelations of economic and cultural elements. There are clear indications in his more recent writings, including the unfinished paper that follows, and in conversations with him over the past year, of increasing concentration on the implications of changes in communications for economic thought and policy; questions concerning the consequences of disequilibrium in the communications area for the study of business disturbance, the strength of nationalism in economic writings ("What produces economists?"), bring out very clearly the direction in which he was proceeding at the end.

Looking back on the course he pursued so steadily, I find it difficult to escape the conclusion that some such road as that he followed is the road all economic historians will follow, if they go far enough.

W. T. EASTERBROOK

University of Toronto

III

It is not possible to discuss in a few pages Harold Innis' contribution to scholarship. I can only hint at it. Perhaps I can best do that by acknowledging the great debt which The Rockefeller Foundation owes him. He, seconded by Anne Bezanson, a Canadian on this side of the border, guided our modest grants in Canada.

I never knew a person who cared more deeply for excellence than Harold Innis. I never knew a person who had a more catholic sense of what excellence consists of than Harold Innis. He understood, as few did, the difficulty and majesty of the task in the social sciences. To him, excellence started within the individual, with what he brought of himself to the task and with what he demanded of himself. Men who dipped from shallow pools or fetid pools had no standing with him. Only the best in quality of mind, in range of outlook, in diligence at getting at all the facts, and in integrity of scholarly spirit, was good enough for him.

One of the privileges of being an officer of The Rockefeller Foundation is that such men as Innis so generously share their scholarship, their wisdom, their insight, and their integrity with us. Such counsel saves a foundation from the many mistakes that might arise from policies determined entirely from within.

From here on I will speak to you in the words of Innis himself taken from letters written by him to Foundation officers between 1940 and 1952. These words will, I think, remind us that Harold Innis was not merely a great social scientist; he was a humanist as well.

> The cultivated mind has been forfeited to the demand for superficiality; as a result, attempts to secure a proper perspective on life have been almost completely unsuccessful.
>
> . . . . .
>
> There is no appreciation whatever of the philosophical problems of statecraft in a democratic society, simply an assumption that science can tell statesmen how to push people around without its being known that they are being pushed around.
>
> Your grant to economic history was a bold, imaginative stroke designed to check the obsession with the immediate which has become the most serious menace of social science and especially of economics. The struggle for a concern with time is a struggle against tremendous odds. In the general strategy, devices must be worked out which will enable scholars to concentrate on work involving a substantial part of their lives.
>
> . . . . .
>
> As I indicated in conversation, I would hope that determined efforts could be made to prevent a further widening of the gap between the humanities and the social sciences and to bring them closer together. Failure to realize the significance of this problem implies sterility in both the humanities and the social sciences. One would hope that great efforts can be made to bring about a happier relation.
>
> . . . . .
>
> Since seeing you, I have spent two or three days with university presidents at Hamilton—Canadian Universities Congress. Seriously, your plan of

starting a consultant job to pick university presidents ought to be put into effect immediately.

. . . . . .

In Canada, university presidents are in the habit of talking about the Arts courses, and at intervals of four or five years pulling the whole structure out by the roots, and locking at them, and then replanting them and wondering why they don't flourish. If a university president would concentrate on the very important job of making appointments and defending them after they are made, the Arts courses might have a chance, but apparently that is not enough and they must spend their time setting a bad example by tinkering with courses.

. . . . . .

I have been tempted to write a blast suggesting the inevitable defeat of American policy partly based on the problem of language and propaganda. It proved impossible for Germany, as it will prove impossible for any group, to penetrate the Russian language. But there are many other factors. I do not believe that American self-confidence is sufficient to admit of wise delayed moves. The interest in propaganda defeats a masterly waiting policy, and no people can be great unless they learn when not to do things and when to do them and to have the self-confidence enabling them to make decisions in their own way and in their own time. The Romans and the British to some extent learned this.

. . . . . .

I think there are dangers in the pretensions of precision. A friend of mine has been described as more anxious to be precise than accurate, and I suspect that we are in danger of this general disease in the social sciences. As Frank Knight put it, we deal in the averages of estimates and these are not very precise. But I am afraid we deal also in specific measurements and are greatly attracted to things which can be specifically measured. For all this, of course, there is a very important place, but it is a limited place, and its limits ought to be very carefully studied.

I keep coming back to my own particular interests in what I laughingly call "research," namely, the persistent tendency in the field of knowledge and in the social sciences to build up monopoly or oligopoly situations. The literature builds up around the name of Keynes, or Marx, or someone else, and everything else is dropped. A situation responsible for these tendencies is dangerous and comes a little short of dictatorship; that is, the difference between oligopoly and monopoly is not much, but it is important. What I am wondering about is whether we can reach a position in which there is continuous discussion of vital problems. Problems cease when they become unmanageable or monopolies. And this is why I would like to see the drift toward the humanities—namely, to recognize the intensive work which has been done over the centuries and not so completely ignore it as is now done, or to put it in the form of first-year survey courses, which is probably worse. Such a drift might do something

to make one alert to the possibilities of the social science of totalitarianism which have become so threatening.

. . . . .

I have just been to Chicago (A.E.A.) and have come away disappointed. Too many papers on legislation—really a small branch of the Bar Association. Not a single comment from the floor on papers dealing with theory, suggesting that no one could understand highly mathematical papers read from the floor. Douglas gave a rather masterly presidential address.

I have been struck by the interest in aggregates and averages and the consequent decline of interest in reforms. The new interest in mass manipulation seems to be taking the zeal out of interest in reforms. In other words, reforms are now trivial matters and the concern is with legislation and administrative detail.

. . . . .

The great problem in the American Economic Association is to check this tendency to splinter groups and to split up economic knowledge into little groups with vested interests of their own in publications, and in meetings, joint or otherwise. The prospect of emphasizing a theoretical, universal, and all-inclusive approach is, in consequence, very difficult.

. . . . .

I could easily imagine Harold Innis saying to me the words once used by the late Robert Warren: "No economist is worth a damn if he doesn't have integrity."

Whatever the influence of Harold Innis effectively touched, there was quality as a result.

J. H. WILLITS

Rockefeller Foundation

THE DECLINE IN THE EFFICIENCY OF INSTRUMENTS ESSENTIAL IN EQUILIBRIUM[1]

Note: The untimely death of Professor Harold A. Innis on November 8, 1952 deprived this Association of the presidential address that he was to have delivered at the December 1952 meetings—an address which all acquainted with him or his work knew would be not only humorous and filled with incisive comments but intensely thought-provoking. However, we do have a preliminary draft of the first portion of his intended address. It should be remembered that the portion printed here was written when he was extremely weak and often in much pain. No doubt it would have been extensively revised and more closely knit together had he survived to complete it. This fragment, though very typical of the author, is essentially introductory in character. It barely reaches the point where he begins to develop his real subject and does not make clear the main thesis he had intended to expound. Fortunately, however, during the summer, he had discussed his proposed address at considerable length with his oldest son, Donald Innis, who has kindly prepared the brief summary included here, covering the main points which his father had intended to develop.

CHESTER W. WRIGHT

When my friend Bob Coats as federal statistician became president of the American Statistical Association under circumstances similar to my own in relation to this Association, he compared himself to James VI of Scotland who became, as you remember, James I of England; and he drew interesting parallels between the interventions from the north to the south in the two cases. I am too aware of the ultimate fate of the Stuarts, in particular of Charles I, the son of James, to wish to press this comparison further. But I must begin this paper with remarks which may be helpful to you in explaining its contents. A social scientist in Canada can only survive by virtue of a sense of humor. (Stephen Leacock was a logical result.) He can scarcely fail to be amused by the goings on in this country and by the antics of Great Britain, or fail to be disturbed by a realization that he can do nothing about it. Occasionally he is described in after-dinner speeches as an interpreter between the two countries as though anyone could interpret for individuals who betray such unmistakable evidence of lunacy. In a sense, perhaps, a realization that he lives in such a large insane asylum may be an indication of sanity, but it is unavoidable that he should have serious doubts about his own sanity. My old friend the late Professor Robert McQueen used to write from Winnipeg, half in earnest half in jest, "I'm depressed and fear I'm becoming known as a luncheon speaker. Can't you do something to get me an honest job?" For these reasons the

[1] Alternative titles on the manuscript are: "The Bias of Economics" and "The Menace of Absolutism in Time."

social scientist must do his best to maintain a sense of humor or a sense of balance, and if he appears on occasion to strain for effects I hope he will be forgiven. It is dangerous to appear humorous at the expense of one's elders or, as the Anglican prayer book has it, "one's betters" and I hope that anything I have said will be accepted in the proper spirit. We can at least say that we have a properly developed inferiority complex and know our places.

My appointment is a tribute to the toleration of the social sciences—a recognition of the capacity of a subject to overlook regions and nationalities and bifurcations within the social sciences even to the lowest stratum of the economic historian. An expression of this tolerance has not been achieved without recognition of the importance of political devices in checking the disastrous effects of a majority vote with concentration on the election of representatives from densely populated areas. I know that someone will be muttering that majorities also have rights, and it may be that when that awful day of judgment arrives when someone writes a doctor's thesis on the presidential addresses of this Association, as has been done for the American Historical Association, the claims of majorities will be justified.

The limitations of tolerance have of course been evident. Candid observers have expressed regrets at the relative neglect of problems of economic theory or of universal problems and the increasing prominence of sessions concerned with specifically American problems—indeed specifically American legislation. Groups with specialized interests have hived off from the Association, including a group in which I have a special interest, namely economic history, and have set up their own side shows outside the main tent; or they have seen the space outside crowded and have preferred to carve out places for themselves within the main tent and form what a predecessor of mine has called splinter groups. The climax has perhaps been reached with the selection of a president from one such group. The responsibility of the president for the general programme makes him aware of the difficulties he has created, partly through the warnings of his predecessors and partly through his own experience. In other words I am in the position of the man who was about to be hung; when he was asked whether he had anything to say, he replied "This will certainly teach me a lesson."

Having learned my lesson, I must begin by pleading for a general emphasis on a universal approach and by insisting as an economist that economic history is primarily concerned with the task of extending the universal applicability of economic theory and of strengthening a central core of interest. In the words of Plato the task of all knowledge is to discover "the limits and proportions of things." The economic historian must test the tools of economic analysis by applying them

to a broad canvas and by suggesting their possibilities and limitations when applied to other language or cultural groups. How far, for example, are we justified in asking students from other societies essentially agricultural—let us say the Chinese—to conform to the tests applied in doctorate examinations primarily reflecting the characteristics of a system which has grown up in relation to an industrial society? The problem of semantics alone compels resort to the devices of the parrot in reliance on memory. Graham Wallas as a result of his wide experience with Indian students has reminded us that the English language has only slight emotional associations for them, that examinations emphasize only phrases and words of books and that training in English for the Indian civil service probably produced results similar to the results in the Chinese civil service.[2]

Within the West itself the problem of communication is scarcely less acute. In European countries more profoundly influenced by canon law and Roman law the social sciences develop along different lines than in Anglo-Saxon common law countries. Talcott Parsons has suggested possible common ground but it may be questioned whether he recognized sufficiently the contrast between the work of Pantaleoni (and his emphasis on mathematical economics and in turn his influence on Pareto) and that of common law economists. The impact of Pareto's training in engineering and in science was evident in a concern with the mathematical approach to the social sciences. In turn Pareto was compelled to write a sociology to accompany his rational approach—a phenomenon with little precedent in the Anglo-Saxon world.

The problem of the application of theory becomes even more serious. The significance of language as a differentiating factor in Europe has probably increased with the telephone and radio. In turn statistics will vary in their significance as national groups, based to an important extent on language, tend to concentrate on the range of statistics which show their pre-eminence in various lines, particularly those which emphasize the largest elements or those increasing most rapidly in their societies. Progress has been defined as that kind of effort that can be measured in statistics. Statistics tend to take the heart out of mathematics. They are collected with relation to specific distinctive problems of states with different constitutions, federal and unitary. They are suppressed and distorted for military purposes and their value depends much on the literacy of the populations concerned. The significance of Keynesian economics to administrative systems limits possibilities of comparison. Statistical calculations which become a basis of national policy have implications for statistics compiled later in relation to the effects of the policy and make comparisons with other nations more

[2] *The Art of Thought* (London, 1926), p. 254.

difficult. Nature copies art. Monetary manipulations and tariff adjustments reflect and intensify the significance of vernaculars, particularly as effected by journalism and the radio and have their implications for statistics. We are familiar with the efforts of Colin Clark to overcome these difficulties but we can scarcely be unaware of the limitations of his work. An obsession with statistics determined by national boundaries increases the dangers of frictions of political entities.

The significance of statistics will vary with attitudes toward the state. A census may be conducted for military purposes, and the scriptural injunctions against enumeration are not without foundation; or for purposes of more adequate distribution of tax and other burdens, including railway rates. In the patriarchal traditions of Roman law the state has been regarded as an instrument of oppression and the proposals of Marx and Lenin assumed a withering of this concept of the state and substitution of the worker for the bourgeoisie. The rapidity of the spread of capitalism reflects the character of the state. In Sweden and in Australia the industrial revolution was comparatively late with the result that a soft capitalism was accompanied by nationalization, co-operative movements and labour governments. In Russia the state as an instrument of power was used conspicuously to overcome the difficulties of the frontier, notably in building the trans-Siberian railway, and much the same might be said of Canada in extending railways to the Pacific.

If we narrow our concern to countries in which common law plays an important rôle we are by no means free of difficulties. The concept of possession in common law and in German law essential to the expansion of commerce and of economics in contrast with the concept of absolute ownership in Roman law is by no means a guarantee of uniformity. Bryce remarked that

> The more any department of law lies within the domain of economic interest, the more do the rules that belong to it tend to become the same in all countries, for in the domain of economic interest Reason and Science have full play. But the more the element of human emotion enters any department of law, as for instance that which deals with the relations of husband and wife, or of parent and child, or that which defines the freedom of the individual as against the State, the greater becomes the probability that existing divergences between the laws of different countries may in that department continue, or even that new divergences may appear.[8]

Sir Frederick Pollock has pointed to the bias of the common law toward competition in that it must draw its resources from contentions between competitors. The character and frequency of disputes are important elements determining the profits of the legal profession. But Holmes

[8] Bryce, *Studies in History and Jurisprudence,* Vol. I, p. 123.

has stated that a constitution "is not intended to embody a particular economic theory whether of paternalism and its organic relation of the citizen to the state, or of *laissez-faire*." Pollock complained that case law had been largely modified by doctrines in favour among economists and publicists and that "judges ought to be very careful about committing themselves to fashionable economic theories."[4] Failure to protect themselves was almost certain in his opinion to involve mistakes to be remedied by legislative amendment which is sure to be unsatisfactory. We may well ask how far economics has become an indication of the lag between case law and public opinion and how far legislation is a result of the efforts of economists to hasten changes in case law. Certainly the enormous expansion of legislation reflects an unhappy relationship between economics and law. Many of you will be familiar with the problem of an economist who appears as a witness and who makes statements in a written brief which are regarded by lawyers as concessions to the enemy. In turn economists acting as arbitrators become annoyed with the tactics of lawyers and favour the appearance of concessions as an indication of truth.

Changes in attitudes toward common law vary as between different countries and within the same country as between different periods, and will depend to an important extent on differences in the character of economic life particularly as reflected in the division of labour and in trade. These in turn will vary with the effectiveness with which information can be made available regarding commodities to be exchanged. Highly developed media of communication will become evident in the emergence of organized exchanges but the effects of inaccurate and inadequate information will be apparent in outbursts such as the South Sea Bubble and the various phenomena described by Arthur H. Cole and Charles Mackay and such as appeared in real estate booms in the cities of this continent, especially in Western Canada, and in gold rushes.

As information was handled more efficiently dangers of fanatical outbreaks became less acute. Quetelet in 1835 commented on the influence of an expanding press in checking tendencies toward revolution. It had "singulièrement contribué à faciliter la réaction et par suite à rendre les grandes revolutions à peu près impossibles; elle presente cet avantage immense qu'elle ne permet pas aux forces de s'accummuler d'une manière effrayante, et que la reaction se manifeste presque aussitôt après l'action, quelquefois même avant que l'action ait eu le temps de se propager."[5] The invention of the telegraph and its

[4] Pollock, *Genius of the Common Law*, p. 108.

[5] A. Quetelet, *Sur L'Homme* (Paris, 1835), Vol. I, p. 290.

rapid extension in continental land areas and in submarine cables enormously enhanced the availability and the accuracy of information for the purposes of trade. It fostered demands for the equalization of accessibility. Newspapers in Chicago, especially the *Chicago Tribune,* protested vigorously in the early 'sixties against the exploitation by New York interests of the difference in time between the two cities. Western papers were compelled to pay high rates for market reports controlled by New York interests in the Associated Press of that day. The regional monopoly was gradually weakened in the latter half of the nineteenth century and came to an end finally with the formation of the Associated Press.

By this time my bias will have begun to wear thin and in fairness I should indicate its character in so far as my limitations permit. I have been primarily interested in the economic history of Canada and in particular factors which explain its peculiarities, especially the successive importance of staple raw materials to mention fur, fish, lumber, wheat, minerals and pulp and paper. I am concerned in this presidential address with the problems inherent in the pulp and paper industry as related to the production of information for purposes of trade and the efficiency of the price system. The industry occupies a peculiar position in that it is protected by the Bill of Rights in the American Constitution and by its possibilities of control over public opinion. Possible checks through the development of legislation in raw material producing regions, for example the provinces of Canada, have been offset by vertical integration in which large American newspapers control their own industrial operations in Canada.

The effects of the enormous expansion in the production of raw material following improvements in technology in the use of wood were evident in the sharp decline in prices of newsprint in the later part of the 19th century and in the expansion in the production of information by newspapers. The monopoly of the Associated Press evident chiefly in the control of morning and Republican newspapers was offset by the development of the Hearst Press and the International News Service and by the development of the cheap press concerned primarily with evening papers by the Scripps, McRae, Howard interests in the United Press. The impact on information can be suggested in one or two illustrations. Lowering of the price of the newspaper was dependent in part on the denominations of money used in various cities. In Chicago and in St. Louis the mint was persuaded to distribute quantities of pennies and department stores co-operated by advertising goods for odd amounts and thus hastening the use of small denominations. In San Francisco on the other hand Scripps papers were handicapped by customs continued from the gold rush period which implied refusal

to recognize small denominations. In the Yukon Territory as late as 1926 coins smaller than 25 cents were regarded with disfavour. The drive for cheaper information regarding prices, especially in department stores, had important implications for the currency structure and for velocity of circulation. The broad implications of prices of newsprint for the distribution of information in large cities were paralleled by developments on a wider field. During the second world war high cable rates to Australia were reduced by subsidy and the position of Australia in the information field greatly strengthened whereas the high rates to Spain were said to play an important rôle in keeping Franco out of the war.

An increase in the circulation of newspapers and a policy of low fixed prices designed to facilitate increased circulation were paralleled by the increasing importance of advertising as a source of revenue and the necessity of developing policies to attract advertising. The newspapers played an important rôle in the building up of the great department stores as distributing organizations and also in changes in the methods of production. In England for example the *Daily Mail*[6] found itself faced with the problem of finding industries with a productive capacity adequate to the demands of purchasers created by advertising. Drapers as advertisers were limited by their capacities to supply particular articles. In a systematic search for industries with relatively inexhaustible capacities of production the *Daily Mail* concentrated on the building industry and on a system of advertising developed beyond the immediate possibilities of the paper itself. The Ideal Home Exhibition was organized to supplement the newspaper. The newspaper is concerned in a search for mass production industries to meet its advertising requirements. Its position leads it to take a critical attitude towards trusts[7] as narrowing the market or towards the domination of government by powerful groups. Edward W. Bok concentrated his attention on the position of women as purchasers. He was said to have changed the physical appearance of domestic furniture, eliminated the parlor from domestic architecture and persuaded the Castles to introduce more and better dances.[8]

HAROLD INNIS

COMMENT

During the summer I talked to my father a good deal and on several occasions we discussed the subject of his presidential address to this Associa-

[6] See Wareham Smith, *Spilt Ink* (London, 1932), pp. 67 ff.

[7] For a discussion of the suit of Lever Brothers against Northcliffe see Smith, *ibid.*

[8] Lloyd Morris, *Postscript to Yesterday—the Last Fifty Years* (New York, 1947), pp. 269-75.

tion. When I discovered that the notes which he left did not mention the subject which we had discussed I thought that I should offer to present some idea of what he had intended to say. I cannot, of course, present his idea as he would have presented it. I do not know what illustrations and stories he would have used nor can I imagine how his idea would have developed in the course of time. I shall try to present his idea with as few of my own thoughts as possible.

As the subject of his address he wanted to consider the idea that America's strongest tradition is that she has no tradition. America means the United States, but in most cases these remarks apply also to Canada. During our talks we often discussed my trip to Europe in the spring. I had been greatly impressed in Europe—especially in France where I spent most of my time—by the intense and active cultural life of the people. Plays, operas, symphonies, paintings, books and even movies seemed to be active media of communication in France. People seemed to think in terms of these arts and they seemed to regard state-supported theatres, opera houses and radio networks as normal and useful parts of their society. I asked my father why people in North America don't take much interest in these activities since they aspire to have a high level of culture. He said that Americans thought of these things as being connected with the old world and that Americans have been so anxious to be independent that they have given up a great many means of cultural expression. The American tradition involves a studied lack of interest in the culture of Europe. Actually, my father said, this lack of interest in the European traditions is in itself a tradition; and a tradition which consists of keeping oneself to oneself in both space and time is more stultifying than the traditions which Americans are trying to avoid.

Americans do not like to have any links with the past. They want to be free to question any part of their culture at any time. They do not like to have a large body of accepted opinion however sensible it may be. Americans do not want to admit that there is anything in the past which is better than anything in the present. They refuse to learn anything from the older European countries as these countries represent to Americans "the sort of thing we want to get away from." Americans want to develop a new way of life on a new continent.

The results of this desire for freedom from the past are in some ways unfortunate. My father regarded the media of communication of modern America as a sort of trap from which he could see no escape. In the field of education, for instance, a student who comes to a university is not presented with a body of knowledge which is considered to be fundamental to our society; he is encouraged to take a series of survey courses. The American tradition maintains that people should not be pushed around but Americans are so afraid of this that even the dissemination of ideas and facts is looked upon as a sort of pressure which the student must resist and from which the professor must refrain. It is only in specialized fields that professors can act as authorities. For the body of culture which is common to all citizens there are no authorities and all opinions are of equal value. No matter how carefully and objectively a study of society may be done, anyone is free to dismiss it

as just another idea. The freedom of thought which is so dearly loved in America can become freedom from thought. Politics and the arts are looked upon as subjects which may be interesting to some people and not to others. Symphonies and operas are produced for those who happen to be interested and are not thought of as expressing the culture of the country.

If the student who would learn to know America should try to educate himself through books he will find that his attention is dispersed rather than concentrated on some central trends. The student will not find books which will tell him what kind of a country America is and how new inventions affect the American ideal. Americans seem to be convinced that America is so large and complicated that no generalization can hold true for it. Americans feel that they are free of traditions and they feel that their culture is broader in scope than that of any other country which has ever existed. The booksellers and makers of books reflect this feeling clearly. Books in America tend to spread one's interests wider and wider. They do not comment on or add to a central theme which runs through American life. The attitude to be found in books on all sorts of subjects is that each book is a contribution in some small field which will interest specialists, but no book in America would claim to be of general interest and no writer would try to relate his book to the American culture as a whole. Freedom to the American means refraining from trying to discover any of the enduring characteristics of American culture. The American doesn't want to feel that he is committed to anything. Therefore his attention must always be shallow. The American student almost never finds his way out of this welter of superficiality by reading books. My father was very seriously annoyed about this. It made him feel angry and frustrated to hear the purveyors of education and information insisting on the importance of freedom of the press and of communication while using this same freedom to channel minds into the thin layer of contemporary froth which is the subject of study in American books and schools. My father felt that it would be very difficult for Americans to realize the nature of their predicament. He did not see any method of escaping from a trap in which the media of communication are the stronghold of a dogma.

Perhaps the lack of interest in gathering useful information from the past can be illustrated by referring to the rôle of newspapers in our society. My father often remarked that newspapers and superficiality are synonomous. Newspapers must always produce something new and interesting and they must never seem to be interested in anything that is old. Newspapers cannot be concerned with origins nor with the foundations of society, so that the effect of newspapers on society must be to disperse attempts at profound thinking and attempts at building up a body of tradition. My father used to say that newspapers have to keep stirring up the animals. For a potential reader to be satisfied with the contemplation of a traditional body of culture is a very unsatisfactory state of affairs for a newspaper. Newspapers are concerned with the immediate present and the immediate future and their success reflects similar interests in a large part of the population.

Radio programs reflect these tendencies and reinforce them even more.

Radio has no very long past and cannot be interested in evoking the past nor in showing the unity of past and present.

To summarize these remarks—Americans tend to be interested primarily in the present and they do not like to rely on traditional solutions to such problems as present themselves. It might be more accurate to say that Americans think of themselves as trail blazers living in a world so new that traditions can be of little value. My father felt that this attitude was very dangerous because—in so far as it exists—it deprives Americans of any criteria by which they can judge the state of their country or compare it with other countries. When definitions of progress also progress there are no standards by which progress can be measured. George Orwell's book *1984* describes a country in which the newspapers present each item of news as the fruit of progress which they depict as having always been aimed at this goal.

My father thought that the origin of America's conscious scorn for tradition derives from the tradition of the frontier. The people of the United States have built up a new country in a new continent. Americans have become rich and contented by developing the resources of the new world and they have felt that they brought about this state of well-being by the work of their own hands. Americans have felt and still feel that they owe the old world nothing. Americans do not want to be interested in the continent from which they came. They refuse to compete with European countries in art or in any other traditional means of expression. Thus the American tradition is to refuse to have a tradition. Instead of escaping from tradition America has developed and obeyed her own tradition slavishly.

The American tradition of not being interested in the past has meant a concentration on immediacy. The range of interests and means of expression of modern American culture are severely limited by her refusal to be interested in any media of communication which have been used before. America's tradition will make it very difficult for her to go beyond the narrow range of interests which she has set for herself, but until she does go beyond these limits her culture must retain the difficulties and dangers which it now has.

This idea, that America is blindly holding onto the tradition that she has no tradition, is the subject for a presidential address that my father and I discussed last summer.

DONALD INNIS

THE MEANING OF UTILITY MEASUREMENT

By Armen A. Alchian*

Economists struggling to keep abreast of current developments may well be exasperated by the resurgence of measurability of utility. After all, the indifference curve analysis was popularized little over ten years ago amidst the contradictory proclamations that it eliminated, modified, and strengthened the rôle of utility. Even yet there is confusion, induced partly by careless reading and exposition of the indifference curve analysis and partly by misunderstandings of the purposes and implications of utility measurement. This paper attempts to clarify the rôle and meaning of the recent revival of measurement of utility in economic theory and of the meaning of certain concepts and operations commonly used in utility theory.

Measurement in its broadest sense is the assignment of numbers to entities. The process of measurement has three aspects which should be distinguished at the outset. First is the purpose of measurement, second is the process by which one measures something, *i.e.*, assigns numerical values to some aspect of an entity, and the third is the arbitrariness, or uniqueness, of the set of numerical values inherent in the purpose and process. In the first part of this paper we briefly explore the idea of arbitrariness or uniqueness of numbers assigned by a measurement process. In Part II we state some purposes of utility measurement. In Part III we examine a method of measuring utility, the purpose of the measurement and the extent to which the measurement is unique. In Part IV we look at some implications of the earlier discussion.[1]

* The author is associate professor of economics at the University of California, Los Angeles. He wishes to acknowledge gratefully the aid of Norman Dalkey and Harry Markowitz, both of The RAND Corporation. The patient explanations of Dalkey in answering innumerable questions overcame early impulses to abandon the attempt to understand recent utility literature. Markowitz detected several ambiguities and errors in earlier drafts of this exposition. Since neither has seen the final draft they must be relieved of responsibility for remaining errors and ambiguities.

[1] The explanation assumes no mathematical background and is on an elementary level. This paper is not original in any of its ideas, nor is it a general review of utility and demand theory. It is merely a statement of some propositions that may help the reader separate the chaff from the wheat. It may even make clear to the reader, as it did to the writer, one meaning of utility. Most of the material presented here is contained in J. Marschak, "Rational Behavior, Uncertain Prospects and Measurable Utility," *Econometrica* (April 1950), XVIII, 111-41, an article written for the mathematically mature.

I. *Degree of Measurability*

The columns of Table I are sequences of numbers illustrating the concept of the "degree of measurability." The entities, some aspect of which we wish to measure, are denoted by letters. Later we shall discuss the meaning of these entities. Our first task is to explain the difference between monotone transformations and linear transformations.

TABLE I.—ILLUSTRATION OF TYPES OF MEASUREMENT

Entities	Alternative Measures of "Utility"								
	1	2	3	4	5	6	7	8	9
A	1	2	6	11	2	6	5	6	3
B	2	4	7	12	4	12	7	10	7
C	3	5	8	13	6	18	9	14	13
D	4	8	9	14	8	24	11	18	21
E	5	11	10	15	10	30	13	22	31
F	7	14	12	17	14	42	17	30	43
G	11	22	16	21	22	66	25	46	57
H	14	28	19	24	28	84	31	58	73
I	16	33	21	26	32	96	35	66	91
J	17	34	22	27	34	102	37	70	111

We shall begin with monotone transformations and then come to linear transformations via two of its special cases, additive and multiplicative constants.

Monotone Transformations

Let there be assigned a numerical magnitude (measure) to each entity concerned. For example in Table I, for the ten entities, A-J, listed in the extreme left-hand column, nine different sets of numbers are utilized to assign nine different numbers to each of the entities. If two sets of numbers (measures) result in the same ranking or ordering of the entities (according to the numbers assigned), then the two sets are *monotone transformations* of each other. In Table I it will be seen that all nine measures give the same ranking, thus all nine measures are monotone transformations of each other. If this property holds true over the entire class of entities concerned, then the two measures are monotone transformations of each other for that class of entities. The possible set of monotone transformations obviously is very large.

A bibliography is included, to which those who might wish to read more deeply should refer. Excellent starting points are M. Friedman and L. J. Savage, "The Utility Analysis of Choices Involving Risk," *Jour. Pol. Econ.* (Aug. 1948), LVI, 279-304, and J. Marschak, "Why 'Should' Statisticians and Businessmen Maximize 'Moral Expectation'?", *Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability* (Berkeley, University of California Press, 1951), pp. 493-506.

Linear Transformations: Additive Constants

We shall approach the linear transformation by considering two special forms. Look at the numbers in column 3. They are the same as those in 1 except that a constant has been added, in this case 5, *i.e.*, they are the *same "up to"* (except for) an *additive constant.* The measure in column 4 is equivalent to that in column 1 with 10 added. Columns 1, 3 and 4 are *transforms* of each other "up to" (by means of) *additive constants*. This can also be expressed by saying they are equivalent except for an additive constant. The term "up to" implies that we may go through some simpler types. For example, all the transforms up to an additive constant are also contained in the larger, less restricted class of possible transforms known as monotone transforms. An additive constant is a quite strong restriction, even though it may not seem so at first since there is an unlimited number of available constants. But relative to the range of possibilities in the general linear transformations this is very restrictive indeed.

Linear Transformations: Multiplicative Constants

Now look at column 5. It is equivalent to column 1 except for multiplication by a constant, in this case, 2. Column 5 is a monotone transform of column 1, and it is also a "multiplicative by a constant" transform of column 1. Column 6 is column 1 multiplied by 6. Thus, while columns 1, 5 and 6 are monotone transforms of each other, they are also a more particular type of transform. They are transforms up to a multiplicative constant. These are special cases of linear transformations which we shall now discuss.

General Linear Transformations

The numbers of column 7 are equivalent to column 1 except for multiplication by 2 and addition of 3. Letting y denote the numbers or "measures" in column 7 and x those of column 1, we have $y = 2x + 3$. Column 8 is derived similarly from column 1; the multiplier is 4 and the added constant is 2. Column 8 is given by $4x + 2$, but a little inspection will show that column 8 can be derived from column 7 by the same process of multiplying and adding. In this case column 8 is obtained from column 7 by multiplying by 2 and adding -4. Columns 1, 7 and 8 are thus "linear transforms" of each other. This is also expressed by saying that they are the same measures "up to a linear transformation"; that is, any one of these measures can be obtained from any other one by simply selecting appropriate constants for multiplication and addition.

There is a particular property of the linear transformation that has

historical significance in economics. Look at the way the numbers change as one moves from entity to entity. For example, consider columns 1 and 7. The numerical change from entity E to entity F has a value of 2 in the measure of column 1, while in the measure of column 7, it has a numerical value of 4. From F to G the change is 4 in measure 1, and in measure 7 it is 8. If the increment is positive, it will be positive in all sequences which are linear transforms of this particular sequence. But this is true also for all monotone transformations—a much broader class of transformations or measures. Of greater significance, however, is the following attribute of linear transforms: if the differences between the numbers in one of the sequences increases (or decreases) from entity to entity, then the differences between the numbers of these same entities in all of its *linear* transformations will also be increasing (or decreasing). In general, the property of increasing or decreasing increments is not affected by switching from one sequence of numbers to any linear transformation of that given sequence. In mathematical terms, the sign of the second differences of a sequence of numbers is invariant to linear transformations of that sequence.[2] The significance of invariance will be discussed later, but we should note that this property of increasing (or decreasing) differences between the numbers assigned to pairs of entities is nothing but increasing marginal utility—if one christens the assigned numbers "utilities."

II. *Purpose of Measurement*

Order

In the nine columns of Table I are nine "different" measures of some particular aspect of the entities denoted A, B, C, . . . J. How different are they? We have already answered this. Which is the "right" one? This depends upon what one wants to do with the entities and the numbers. It would be more useful to ask which one is a *satisfactory* measure, for then it is clear that we must make explicit for what it is to be satisfactory.[3] For example, if my sole concern were to predict which of the entities would be the heaviest, the next heaviest, etc., I could, by successively comparing pairs in a balancing scale, completely order the entities. [Having done so, I could then assign the numbers in *any* one of columns 1 through 9] so long as I assign the biggest number to the heaviest, and so on down. This means that for the purpose of indicating *order,* any one of the monotone transforms is acceptable.

[2] In monotonic transformations the sign of the *first* differences only are necessarily left undisturbed.

[3] A pause to reflect will reveal that there is a second problem besides that of deciding what "satisfactory" means. This second problem, which we have so far begged, is: "How does one assign numbers to entities?" It is deferred to the following section.

The remaining task is to determine whether the order is "correctly" stated; the fact that the order is the same, no matter which one of the above transforms is used, does not imply that the order is correct. What do we mean by "correctly"? We mean that our stated or predicted order is matched by the order revealed by some other observable ordering process. You could put the entities on some new weighing scales (the new scales are the "test"), and then a matching of the order derived from the new scales with our stated order is a verification of the correctness (predictive validity) of our first ordering. Any monotone transform of one valid ordering number sequence is *for the purpose* in this illustration *completely equivalent* to the numbers actually used. That is, any one of the possible monotone transformations is just as good as any other.

We may summarize by saying that, given a method for validly ordering entities, any monotone transformation of the particular numerical values assigned in the ordering process will be equally satisfactory. We may be technical and say that "all measures of order are equivalent up to (except for being) monotone transformations." Or, in other words, a method of validly denoting *order* only, is not capable of uniquely identifying a particular set of numbers as *the* correct one. Any monotonic transformation will do exactly as well. The degree of uniqueness of an ordering can also be described by saying it is only as unique as the set of monotone transformations. Thus, we often see the expression that "ordering is unique up to a monotone transformation."

Ordering Groups of Entities

But suppose our purpose were different. Suppose we want to be able to order *groups* of entities according to their weights. More precisely, suppose we want to assign numbers to each of the component objects so that when we combine the objects into sets or bundles we can order the weights of the composite bundles, knowing only the individually valid numbers assigned to each component, by *merely adding* together the numbers assigned to each component. And we want to be able to do this for any possible combination of the objects. Fortunately, man has discerned a way to do this for weights. The numbers which are assigned by this discovered process are arbitrary up to a multiplicative constant (of proportionality), so that the numbers could express either pounds, ounces, tons or grams. That is, we can arbitrarily multiply all the numbers assigned to the various components by any constant we please, without destroying the validity of our resulting numbers for this particular purpose. But we can not use any monotone transformation as we could in the preceding case where our purpose was different.

If we were to add an arbitrary constant to each component's indi-

vidually valid numerical (weight) value we would not be able to add the resulting numbers of each component in order to get a number which would rank the composite bundles. Thus, the numbers we can assign are rather severely constrained. We can not use any linear transformation, but we can use a multiplicative constant, which is a special type of linear transformation. And if we were to "measure" lengths of items so as to be able simply to "add" the numbers to get the lengths of the items laid end to end, we would again find ourselves confined to sequences (measures) with a multiplicative constant as the one available degree of arbitrariness.

Utility and Ordering of Choices

The reader has merely to substitute for the concept of weight, in the earlier example about weight orders, the idea of "preference" and he is in the theory of choice or demand. Economics goes a step further and gives the name "utility" to the numbers. Can we assign a set of numbers (measures) to the various entities and predict that the entity with the largest assigned number (measure) will be chosen? If so, we could christen this measure "utility" and then assert that choices are made so as to maximize utility. It is an easy step to the statement that "you are maximizing your utility," which says no more than that your choice is predictable according to the size of some assigned numbers.[4] For analytical convenience it is customary to postulate that an individual seeks to maximize something subject to some constraints. The thing—or numerical measure of the "thing"—which he seeks to maximize is called "utility." Whether or not utility is some kind of glow or warmth, or happiness, is here irrelevant; all that counts is that we can assign numbers to entities or conditions which a person can strive to realize. Then we say the individual seeks to maximize some function of those numbers. Unfortunately, the term "utility" has by now acquired so many connotations, that it is difficult to realize that for present purposes utility has no more meaning than this. The analysis of individual demand behavior is mathematically describable as the process of maximizing some quantitive measures, or numbers, and we assume that the individual seeks to obtain that combination with the highest choice number, given the purchasing power at his disposal. It might be harmless to call this "utility theory."[5]

[4] The difficult (impossible?) psychological, philosophical step of relating this kind of utility to some *quantity* of *satisfaction, happiness, goodness* or *welfare* is not attempted here.

[5] The author, having so far kept his opinions submerged, is unable to avoid remarking that it would seem "better" to confine utility "theory" to attempts to explain or discern why a person chooses one thing rather than another—at equal price.

Three Types of Choice Predictions

Sure Prospects. Before proceeding further it is necessary to indicate clearly the types of choice that will concern us. The first type of choice is that of selecting among a set of alternative "riskless" choices. A riskless choice, hereafter called a sure prospect, is one such that the chooser knows exactly what he will surely get with each possible choice. To be able to predict the preferred choice means we can assign numbers to the various entities such that the entity with the largest assigned number is the most preferred, the one with the second largest number is the next most preferred, etc. As said earlier, it is customary to christen this numerical magnitude with the name "utility."

An understanding of what is meant by "entity" is essential. An entity denotes any specifiable object, action, event, or set or pattern of such items or actions. It may be an orange, a television set, a glass of milk, a trip to Europe, a particular time profile of income or consumption (*e.g.*, steak every night, or ham every night, or steak and ham on alternate nights), getting married, etc. Identifying an entity exclusively with one single event or action would lead to unnecessary restrictions on the scope of the applicability of the theorem to be presented later.[6]

Groups of Sure Prospects. A second problem of choice prediction would be that of ordering (predicting) choices among riskless *groups* of entities. A riskless group consists of several entities all of which will be surely obtained if that group is chosen. The problem now is to predict the choice among riskless groups knowing only the utilities assigned to the individual entities which have been aggregated into groups. Thus if in Table I we were to assemble the entities A through J into various groups, could we predict the choice among these groups of entities knowing only the utility numbers that were assigned to the component entities for the purpose of the preceding choice problem? Of course we ask this question only on the assumption that the utilities previously assigned to the component entities were valid predictors of choice among the single sure prospects.[7]

Uncertain Prospects. A third type of problem is that of ordering choices among risky choices, or what have been called uncertain prospects. An uncertain prospect is a group of entities, only one entity of

[6] For example, see H. Wold, "Ordinal Preferences or Cardinal Utility? (With Additional Notes by G. L. S. Shackle, L. J. Savage, and H. Wold)"; A. S. Manne, "The Strong Independence Assumption-Gasoline Blends and Probability Mixtures (with Additional Notes by A. Charnes)"; P. Samuelson, "Probability, Utility, and the Independence Axiom"; E. Malinvaud, "Note on Neumann-Morgenstern's Strong Independence Axiom," *Econometrica* (Oct. 1952), XX, 661-79.

[7] For an illustration of this problem of rating a composite bundle by means of the ratings of the ratings of the components, see A. S. Manne, *op. cit.*

which will be realized if that group is chosen. For example, an uncertain prospect might consist of a fountain pen, a radio and an automobile. If that uncertain prospect is chosen, the chooser will surely get one of the three entities, but which one he will actually get is not known in advance. He is not completely ignorant about what will be realized, for it is assumed that he knows the probabilities of realization attached to each of the component entities in an uncertain prospect. For example, the probabilities might have been .5 for the fountain pen, .4 for the radio and .1 for the automobile. These probabilities sum to

TABLE II.—EXAMPLES OF UNCERTAIN PROSPECTS

Uncertain Prospect	Probabilities of getting		
	Pen	Radio	Automobile
1	.5	.4	.1
2	.58	.30	.12
3	.85	.0	.15
4	.0	.99	.01

1.0; one and only one of these entities will be realized. An uncertain prospect is very much like a ticket in a lottery. If there is but one prize, then the uncertain prospect consists of two entities, the prize or the loss of the stake. If there are several prizes, the uncertain prospect consists of several entities—the various prizes and, of course, the loss of the stake (being a loser).

But there is another requirement that we want our prediction process to satisfy. Not only must we be able to predict the choices, but we want to do it in a very simple way. Specifically, we want to be able to look at each component separately, and then from utility measures assigned to the elements, as if they were sure prospects, we want to be able to aggregate the component utility measures into a group utility measure predicting choices among the uncertain prospects. For example, suppose the uncertain prospects consisted of a pen, a radio and an automobile as listed in Table II.

Are there utilities which can be assigned to the pen, the radio and the automobile, so that for the purpose of comparing these four uncertain prospects the same numbers could be used in arriving at utility numbers to be assigned to the uncertain prospects? In particular, can we assign to the pen, the radio and the automobile numbers such that when multiplied by the associated probabilities in each uncertain prospect they will yield a sum (expected utility) for each uncertain prospect, and such that these "expected utilities" would indicate preference?

Before answering we shall briefly indicate why choices among uncertain prospects constitute an important class of situations. Upon reflection it will be seen to be the practically universal problem of choice. Can the reader think of many cases in which he *knows* when making a choice, the outcome of that choice with absolute certainty? In other words, are there many choices—or actions—in life in which the *consequences* can be predicted with absolute certainty? Even the act of purchasing a loaf of bread has an element of uncertainty in its consequences; even the act of paying one's taxes has an element of uncertainty in the consequences involved; even the decision to sit down has an element of uncertainty in the consequence. But to leave the trivial, consider the choice of occupation, purchase of an automobile, house, durable goods, business investment, marriage, having children, insurance, gambling, etc. ad infinitum. Clearly choices among uncertain prospects constitute an extremely large and important class of choices.

III. *Method of Measurement*

So far we have discussed the meaning and purpose of measurement. We turn to the method of measurement recognizing that for each type of choice prediction the method of measurement must have a rationale as well as a purpose. For a moment we can concentrate on the rationale which is properly stated in the form of axioms defining rational behavior.

Sure Prospects

Let us start with a rationale for the first type of choice. We postulate that an individual behaves consistently, *i.e.*, he has a consistent set of preferences; that these preferences are transitive, *i.e.*, if B is preferred to A, and C to B, then C is preferred to A; and that these preferences can be completely described merely by attaching a numerical value to each. An implication of these postulates is that for such individuals we can predict their choices by a numerical variable (utility). Asking the individual to make pairwise comparisons we assign numbers to the sure prospects such that the choice order will be revealed by the size of the numbers attached. The number of pairwise comparisons that the individual must make depends upon how fortunate we are in selecting the pairs for his comparison. If we are so lucky as first to present him a series of pairs of alternatives of sure prospects exactly matching his preference order, the complete ordering of his preferences will be obtained with the minimal amount of pairwise comparisons. Any numbering sequence which gives the most preferred sure prospect the highest number, the second preferred sure prospect the second highest number, etc., will predict his choices according to "utility maximiza-

tion." But any other sequence of numbers could be used so long as it is a *monotone transformation* of the first sequence. And this is exactly the meaning of the statement that utility is *ordinal* and not cardinal. The transitivity postulate enables this pairwise comparison to reveal the complete order of preferences, and the consistency postulate means he would make his choices according to the prediction. Thus if he were to be presented with any two of ten sure prospects, we would predict his taking the one with the higher utility number. If our prediction failed, then one of our postulates would have been denied, and our prediction method would not be valid. A hidden postulate is that the preferences, if transitive and consistent, are stable for the interval involved.[8] Utility for this purpose and by this method is measurable up to a monotonic transformation, *i.e.*, it is ordinal only.

Groups of Sure Prospects

The second type of choice, among *groups* of sure prospects, can be predicted using the same postulates only if we treat each group of sure prospects as a sure prospect. Then by presenting pairs of "groups of sure prospects" we can proceed as in the preceding problem. But the interesting problem here is that of predicting choice among groups of sure prospects (entities) only by knowing valid utility measures for choices among the component sure prospects. Can these utility numbers of the component entities of the group of sure prospects, which are valid for the entities by themselves, be aggregated to obtain a number predicting choice among the groups of sure prospects? In general the answer is "no." Hence, although utility was measurable for the purpose of the kind of prediction in the preceding problem, it is not measurable in the sense that these component measures can be aggregated or combined in any known way to predict choices among *groups* of sure prospects. Utility is "measurable" for one purpose but not for the other.[9]

[8] Some problems involved in this assumption and in its relaxation are discussed by N. Geogescu-Roegen, "The Theory of Choice and the Constancy of Economic Laws," *Quart. Jour. Econ.* (Feb. 1950), LXIV, 125-38.

[9] It is notable that the usual indifference curve analysis is contained in this case. Any *group* of sure prospects (point in the xy plane of an indifference curve diagram) which has more of each element in it than there is in another group of two sure prospects, will be preferred to the latter. And further, if one group of sure prospects has more of one commodity than does the other group of sure prospects, the two groups can be made indifferent by sufficiently increasing the amount of the second commodity in the other group of sure prospects. The indifference curve (utility isoquant) approach does not assign numbers representing utility to the various sure prospects lying along either the horizontal or the vertical axis and then from these numerical values somehow obtain a number which would order choices among the groups of prospects inside the quadrant enclosed by the axes.

Uncertain Prospects

We want to predict choices among uncertain prospects. And we want to make these predictions solely on the basis of the utilities and probabilities attached to the elements of the uncertain prospects.

Without going into too many details an intuitive idea of the content of the axioms used in deriving this kind of measurability will now be given.[10] For expository convenience the statement that the two entities A and B are equally desirable or indifferent will be expressed by A = B; if however A is either preferred to or indifferent to B, the expression will be A $\geq$ B.

(1) For the chooser there is a transitive, complete ordering of all the alternative possible choices so far as his preferences are concerned. That is if C $\geq$ B and B $\geq$ A, then C $\geq$ A.

(2) If among three entities, A, B, and C, C $\geq$ B, and B $\geq$ A, then there is some probability value *p*, for which B is just as desirable as the uncertain prospect consisting of A and C, where A is realizable with probability *p*, and C with probability *l-p*. In our notation: if C $\geq$ B and B $\geq$ A, then there is some *p* for which B = (A, C; *p*), where (A, C; *p*) is the expression for the uncertain prospect in which A will be realized with probability *p*, and otherwise, C will be realized.

(3) Suppose B $\geqq$ A, and let C be any entity. Then (B, C; *p*) $\geqq$ (A, C; *p*) for any *p*. In particular, if A = B, then the prospect comprising A and C, with probability *p* for A and *1-p* for C, will be just as desirable as the uncertain prospect comprised of B and C, with the same probability *p* for B, and *1-p* for C.

(4) In the uncertain prospect comprising A and B with probability *p* for A, it makes no difference what the process is for determining whether A or B is received, just so long as the value of *p* is not changed. Notationally, (A, B; p_1), B; p_2) = (A, B; $p_1 p_2$).

To help understand what these axioms signify we give an example of behavior or situation that is inconsistent with each, except that I can think of no totally unreasonable behavior inconsistent with the first axiom. Behavior inconsistent with the second axiom would be the following: Suppose C is two bars of candy, B is one bar of candy, and A is being shot in the head. Form an uncertain prospect of C and A with probability *p* for C. If there is no *p*, however small or close to zero, which could possibly make one indifferent between the uncertain

[10] This is the method developed by J. von Neumann and P. Morgenstern, *The Theory of Games and Economic Behavior* (Princeton University Press, 1944). A very closely analogous method was suggested in 1926 by F. Ramsey, *The Foundations of Mathematics and Other Logical Essays* (The Humanities Press, N. Y., 1950), pp. 166-90. The neatest, but still very difficult, exposition is by J. Marschak, *op. cit.* Still another statement of essentially the same set of axioms is in Friedman and Savage, *op. cit.*

prospect and B, the one bar of candy, he is rejecting axiom (2). Are such situations purely hypothetical?

The third axiom, sometimes called the "strong independence assumption," has provoked the most vigorous attack and defense. So far no really damaging criticism has been seen. It takes its name from the implication that whatever may be the entity, C, it has no effect on the ranking of the uncertain prospects comprised of A or C and B or C. This kind of independence has nothing whatever to do with independence or complementarity among groups of commodities. Here one does not receive both A and C, or B and C. He gets either A or C in one uncertain prospect, or he gets either B or C in the other. Even if A and C were complements and B and C were substitutes, the ordering would not be affected—this is what the postulate asserts.[11]

Axiom (3) is inconsistent with a situation in which the utility of the act of winning itself depends upon the probability of winning, or more generally if probability itself has utility. For example, at Christmas time, one does not want to know what gift his wife is going to give him; he prefers ignorance to any hints or certainty as to what his gift will be. This is a type of love for gambling. Conversely, one may be indifferent to whether he gets roast beef or ham for dinner, but he does want to know which it will be purely for the sake of knowing, not because it will affect any prior or subsequent choices.

Axiom (4) is inconsistent with a concern or difference in feeling about different ways of determining which entity in an uncertain prospect is actually received even though the various systems all have the same probability. For example, suppose an uncertain prospect had a probability of .25 for one of the entities. It should make no difference whether the probability is based on the toss of two successive coins with heads required on both, or whether it is based on the draw of one white ball from an urn containing one white and three black. But consider the case of the slot machine. Why are there three wheels with many items on each wheel? Why not one big wheel, and why are the spinning wheels in sight? One could instead have a machine with covered wheels. Simply insert a coin, pull the handle and then wait and see what comes out of the machine. Does seeing the wheels go around or seeing how close one came to nearly winning affect the desirability? If observation or knowledge of the number of steps through which the mechanism must pass before reaching the final decision makes any difference, even if the fundamental probability is not subjectively or objectively affected, then axiom (4) is denied.

Implied in the stated axioms is a method for assigning numerical

[11] See the literature listed in footnote 6.

utility values to the various component entities. The method is perhaps explained best by an illustration of the method using the entities of Table I. Take one entity, A, and one other, say B, as the two base entities. Between these two entities you choose B as preferable to A. Now I *arbitrarily* assign (*i.e.*, choose any numbers I wish so long as the number for B exceeds that for A) the number 2 to B and some smaller number, say 1, to A. You then consider entity C, which you assert you prefer to A and to B. The next step is rather involved; I now form an uncertain prospect consisting of C and A. You are now offered a choice between B, a sure prospect, and the uncertain prospect comprised of "A or C", where you get A or C depending upon the outcome of a random draw in which the probability of A is p, otherwise you get C.

You are asked to, and you do, select a value of p which when contained in the uncertain prospect leaves you indifferent between B and the uncertain prospect, "A or C."[12] If p were set at nearly zero, you would choose the uncertain prospect, since C is assumed here to be preferred to A; choosing the uncertain prospect would mean that you would almost surely get C. The converse would be the outcome if p were set at nearly 1. Therefore, some place in between there is a value of p which would leave you indifferent between B and the uncertain prospect of "A or C." After you indicate that value of p, I assign to the uncertain prospect the same number, 2, I did to B since they are equally preferred by you.

Now we may determine a number for C by the following procedure. Treat the probability p, and its complement $1\text{-}p$, as weights to be assigned to the numbers for A and C such that the weighted sum is equal to the number 2, which has been assigned to the uncertain prospect. If, for example, you were indifferent when p was equal to .6, then we have the following definitional equation, where we let U(A) stand for the number assigned to A, U(B) for the number assigned to B, and U(C) for the number assigned to C:

$$U(B) = p \cdot U(A) + (1\text{-}p) \cdot U(C)$$

$$\frac{U(B) - p \cdot U(A)}{(1\text{-}p)} = U(C) = 3.5.$$

Using this convenient formula we can assign numbers to the entities D, E, F by appropriately forming uncertain prospects and letting you determine that value of p which produced indifference. These revealed

[12] It is important to notice that the sure prospect must not be preferred to both of the components of the uncertain prospects, for in that event no probability value would induce indifference.

numbers will completely order the entities. If E has a larger number than G, E will be preferred over G. This assignment of numerical value is made without ever comparing E and G directly. Each has been compared with a base entity. A brief pause to reflect will reveal that in this paragraph we have been specifying a convenient method for manipulating, or combining the "utilities" or "choice indicator numbers" as well as specifying a process of attaching numbers (utilities) to the entities.

It happens that if we insist on using the simple formula above, rather than some more complicated one, the numerical magnitudes assigned by this process are unique up to a linear transformation. For example, suppose that by our process of assigning numbers we obtained the set of numbers in column 3 of Table I for entities A to J. Now, instead of assigning 7 and 6 to B and A, had we decided in the first place to assign a value of 7 to entity B and a value of 5 to entity A, we could have obtained instead the sequence in column 7. Column 7 is a linear transformation of column 3. In other words, we may arbitrarily, at our complete discretion, assign numbers to *two* of the entities; once that has been done, our method will determine the remaining unique numbers to be assigned. But all the various *sets* of numbers (utilities) that could have been obtained, depending upon the two initial numerical values, are linear transformations of each other. Thus, our measurement process is unique "up to" a linear transformation.

If the preceding method of assigning numbers does predict correctly the choice a person actually makes among uncertain prospects, then we have successfully assigned numbers as indicators of choice preferences. We have successfully measured utility and have done it with the convenient computational formula above. Furthermore, every linear transformation of our predicting numbers, "utilities," would be equally valid—or invalid.

In summary, (1) we have found a *way* to assign numbers; (2) for the way suggested, it so happens that the assigned numbers are unique up to linear transformations; (3) the numbers are convenient to manipulate. All this was implicit in our set of postulates. Before asking whether the numbers predict actual behavior, we shall discuss some side issues.

Diminishing or Increasing Marginal Utility

Recalling our earlier exposition of the mathematical properties of linear transformations, we see that in all of the columns (except 2 and 9 which are not linear transformations of the others) the pattern of *increments* between the numbers assigned to entities is similar. For example, between pair H and I on scale 7 the increment is 4 and be-

tween pair I and J it is 2. Moving from H through I to J we have a diminishing increment in the numerical magnitudes assigned. In more familiar terminology we have diminishing marginal utility among H, I and J.[13] Similarly, all the linear transforms of scale 7 will retain this diminishing marginal utility over the range of entities H, I and J. And the suggested way of assigning numbers to the component entities assigns numbers (utilities) which are equivalent up to a linear transformation; that is, any one of the linear transformations will be just as good—for our purposes—as any other of them. By implication we can determine whether there is diminishing or increasing marginal utility.

Maximization of Expected Utility

By this method of assigning utilities we have ordered all the entities. However, our purpose was more than this; otherwise the uniqueness of the numbers up to a linear transformation would have been an unnecessary restriction. As we know, any monotonic transformation would leave order unaffected. The linear transformation restriction is imposed by our desire to predict choices among uncertain prospects from the utilities and probabilities of the component entities and to do it in a convenient form, *viz.*, according to maximization of expected utility.[14]

Implied in our set of postulates is not only the preceding method of assigning numbers for utilities but also (in fact the two are merely two aspects of the same implication) a method for combining the utilities of the component entities into a utility number for the uncertain prospect.

This method is based on the implication that a person who behaves according to the axioms will choose among uncertain prospects according to expected utility. Expected utility is merely the sum of the weighted utilities of the components of the uncertain prospects where the weights are the probabilities associated with each component. In symbolic form

$$U(A \text{ or } B, p) = p\, U(A) + (1\text{-}p)\, U(B)$$

where the expression $U(A \text{ or } B, p)$ denotes the utility of the uncertain prospect of entities A and B in which A will be received with probability p, and B otherwise. For example, we could from any one of our measures in Table I (except columns 2 and 9) predict what one would do when faced with the following choice: he is presented first with an

[13] More strictly we should also have some scale for measuring the amount of H, I and J, either in weight or volume, etc. While the process for assigning these scales also is a complex one, we may pass over it in order to concentrate upon the "utility" measure.

[14] It is not dictated by any nostalgia for diminishing marginal utility.

uncertain prospect containing entities B and C. If he chooses this prospect, his probability of getting B is one-half; otherwise, he will get C. The other uncertain prospect which he is offered contains entities A and E, and if he chooses this prospect his probability of getting *F* is one-fourth—otherwise, he gets A. Our individual will choose the first prospect, no matter which of our acceptable measures we use. We obtain this prediction by multiplying (weighting) the "utility" measures of each entity in each prospect by the probability of that entity. If we use the utility measure of column 8, we have for the first prospect $(\frac{1}{2} \times 14) + (\frac{1}{2} \times 10) = 12$, and for the second prospect, $(\frac{3}{4} \times 6) + (\frac{1}{4} \times 22) = 10$. The first prospect has the larger expected "utility" and will be chosen.[15] How can we justify this procedure of adding the products of probabilities and "measures of utilities" of entities in an uncertain prospect and calling the result "the utility" of the uncertain prospect? The axioms of human behavior on which it is based are those which earlier gave us the procedure for "measuring utility" up to a linear transformation.[16]

Another way to express this implication that a rational person chooses among uncertain prospects so as to maximize expected utility is in terms of the implied shapes of indifference curves in the plane of *probabilities* of the various components of the uncertain prospects.

Suppose that I am indifferent between receiving a watch and receiving \$30.00. In Figure 1a, the horizontal scale measures the probability with which I will get \$30.00 and the vertical axis measures the probability with which I will get the watch. The origin represents the point at which I am sure to get nothing. The point W on the vertical axis presents the situation in which I am sure to get the watch and not get the \$30.00. The point M on the horizontal axis represents the situation in which I am sure to get the money and am sure not to get the watch. A straight line drawn from W to M represents all the various uncertain prospects in which I might get the watch or I might get the money, where the probabilities are given by the horizontal distance for

[15] If column 9 had been used, the chooser would have been declared indifferent, *i.e.*, the two combinations have equal utility. This is inconsistent with the utility value and predictions derived from the measures in the other columns.

[16] If our task is merely to order choice among the uncertain prospects, we could, after obtaining the expected utility of the prospect, obviously perform any monotonic transformation on it without upsetting the order of choices among the uncertain prospects. However, there seems little point in doing so, and there is good reason not to do so. In particular one might wish to predict choices among groups of uncertain prospects where, in each group of prospects, the entities are themselves uncertain prospects. This combination of several uncertain prospects into one resultant uncertain prospect is a consistent operation under the preceding postulates, and the utility measures attached to it will have an implied validity if the utility measures attached to the component prospects, derived in the manner indicated earlier, are valid.

the money and the vertical distance for the watch. Thus, the point P represents the prospect in which I will get the watch with probability ⅔ or otherwise the money (with probability ⅓). The preceding axioms imply that this straight line is an indifference line or utility isoquant. In other words, the utility isoquant is a *straight* line in the space of probabilities, in this case a straight line from one sure prospect (the watch with certainty) to the other equally sure prospect (the $30.00 with certainty).

The straight line utility isoquants need not go from sure prospect to sure prospect, as can be seen from a second example. Suppose that I am

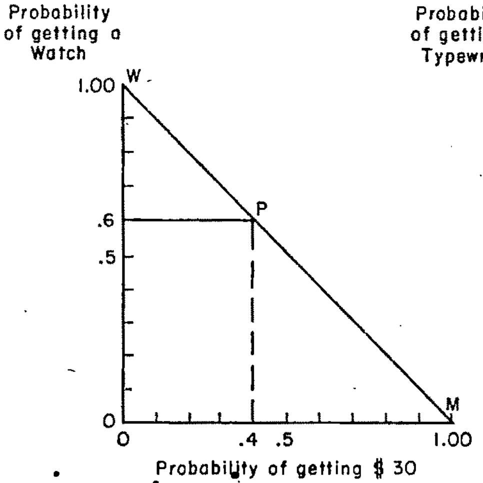

Fig. 1a

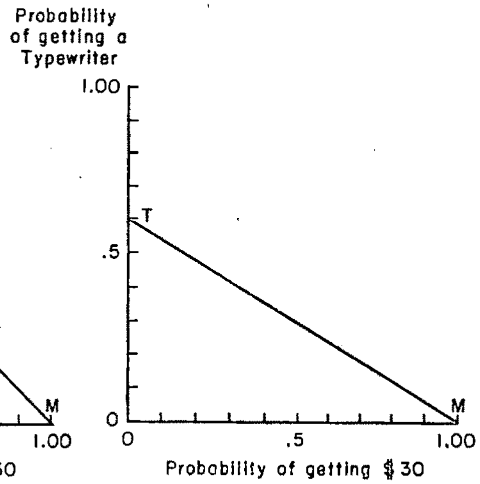

Fig. 1b

indifferent between receiving $30.00 with certainty (sure prospect of $30.00) and the uncertain prospect in which I will get a particular typewriter with probability .6 and nothing with probability .4. In Figure 1b, this latter uncertain prospect is T on the vertical axis. Since I am indifferent between this uncertain prospect T and the $30.00 with certainty (point M) a straight line, TM, is a utility isoquant, and all prospects represented by the points on that line are indifferent to me—have the same utility. In summary, in any such figure, a straight line through any two equally preferred prospects will also contain all prospects (certain and uncertain) that are equally preferred to the first two. This can be generalized into three and more dimensions in which case the straight line becomes a plane surface in three or more dimensions.

The additivity of the simple weighted (by probabilities of the components of the entities) "utilities" enables us to call this composite

utility function a linear utility function. This means that the measure of "utility" of uncertain prospects (in a probability sense) of entities is the sum of the "expectation" of the "utilities" of the component entities; it does not mean that our numerical numbers (measuring utility) assigned to the entities are linear functions of the physical amounts (*e.g.*, weights or counts) of the magnitude entities. Here linearity means that the utility of the uncertain prospects is a linear function of the utility of the component entities; incidentally the utility function is also a linear function of the probabilities of the entities.

IV. *Validity of Measurement*

Has anyone ever succeeded in assigning numbers in this way and did the sequence based on past observations predict accurately the preferences revealed by an *actual* choice among new and genuinely available prospects? The only test of the validity of this whole procedure, of which the author is aware, was performed by Mosteller and Nogee.[17]

The essence of the Mosteller-Nogee experiment was to subject approximately 20 Harvard students and National Guardsmen to the type of choices (indicated above on pages 37-39 required to obtain a utility measure for different entities. In the experiment, the entities were small amounts of money, so that what was being sought was a numerical value of utility to be attached to different amounts of money. After obtaining for each individual a utility measure for various amounts of money, Mosteller and Nogee predicted how each individual would choose among a set of uncertain prospects, where the entities were amounts of money with associated probabilities. Although some predictions were incorrect, a sufficiently large majority of correct predictions led Mosteller and Nogee to conclude that the subjects did choose among uncertain prospects on the basis of the utilities of the amounts of money involved and the probabilities associated with each, *i.e.*, according to maximized expected utility. Perhaps the most important lesson of the experiment was the extreme difficulty of making a really good test of the validity of the implications of the axioms about behavior.

Whether this process will predict choice in any other situation is still unverified. But we can expect it to fail where there are pleasures of gambling and risk-taking, possibly a large class of situations. Pleasures of gambling refers not to the advantages that incur from the possibility of receiving large gains, but rather to the pleasure of the act of gambling or act of taking on extra risk itself. There may be an

[17] F. Mosteller and P. Nogee, "An Experimental Measurement of Utility," *Jour. Pol. Econ.* (Oct. 1951), LIX, 371-404.

exhilaration accompanying sheer chance-taking or winning per se as distinct from the utility of the amount won. Even worse, the preference pattern may change with experience.

V. *Utility of Income*

We can conclude our general exposition with the observation that although the preceding discussion has referred to "entities" we could have always been thinking of different amounts of income or wealth. The reason we did not was that we wanted to emphasize the generality of the choice problem and to emphasize that utility measures are essentially nothing but choice indicators. However, it is useful to consider the utility of income. How do the numerical values (utilities) assigned by the preceding method vary as income varies? Now this apparently sensible question is ambiguous, even after our preceding discussion which we presume to have eliminated confusion about the meaning of "measurability of utility." For the question still remains as to whether the utility measure assumes (1) a utility curve that stays put and along which one can move up and down as income varies; or, (2) a utility curve whose shape is definable only on the basis of the current income as a reference point for change in levels of income. The former interpretation emphasizes dependence of utility on levels of income, while the latter emphasizes the dependence of utility on the changes in income around one's present position.

The most common type of utility curve has been one whose shape and position is independent of the particular income actually being realized at the time the curve of utility of income is constructed. For example, Friedman and Savage draw a utility curve dependent primarily upon levels of income rather than upon changes in income, and it is presumed that individuals choose as if they were moving along that curve.[18] The generic shape of the curve postulated by Friedman and Savage is shown in Figure 2.[19] This shape is supposed to explain the presence of both gambling and insurance. How does it do this?

Reference back to our method of predicting choices among uncertain prospects reminds us that choices will be made so as to maximize expected utility. A graphic interpretation is very simple. In Figure 2, let the income position now existing be A; let the individual be faced with a choice of staying where he is, or of choosing the uncertain prospect of moving to income position B with probability .999 or of moving to income position C with probability .001. Position A represents paying fire insurance, while positions C and B form the uncertain prospect where C is the position if a fire occurs with no insurance and B is the position if no fire occurs with no insurance.

[18] *Op. cit.*

[19] The utility curve is unique up to a linear transformation.

Will he choose the uncertain prospect or the sure position A? The basis for the choice as implied in our postulates can be described graphically as follows: From point B′ draw a straight line to point C′. This straight line gives the expected utility of all uncertain prospects of the incomes B and C as the probability attached to C varies from zero to one. The point on this straight line yielding the expected utility of our uncertain prospect can be found by computing the expected *income*, D; and then rising vertically to point D′ on the straight line

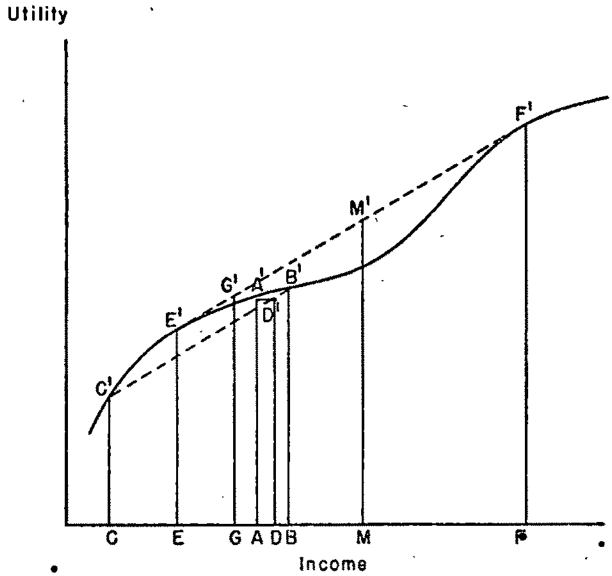

Fig. 2

B′C′. The ordinate DD′ is the expected utility of the uncertain prospect. If the length of DD′ is less than AA′, as it is in our example, where AA′ denotes the utility of the income after taking insurance, then the person will choose the insurance and conversely.

It is apparent that if the utility curve were always convex as in the first and last part of the curve in Figure 2, a person would never choose an uncertain prospect whose expected income was no greater than the insured income position. And if the curve were concave, a person would always choose the uncertain prospect where the expected income was at least equal to the present insured position.

If the curve has the shape postulated by Friedman and Savage, it is possible to explain why a person will take out insurance and will at the same time engage in a gamble. To see how the latter is possible, suppose a person were at position A. At the same time that he might be willing to take out insurance he may also be willing to gamble by

choosing an uncertain prospect of ending up at E or F, despite its lower expected income at G, because the expected utility GG′ of the uncertain prospect is larger than the utility AA′ of position A. Friedman and Savage tentatively attempt to lend some plausibility to this shape of utility curve by conjuring that economic society may be divisible into two general income level classes, the lower one being characterized by the first convex part of the curve and the higher one by the upper convex section. An intermediate group is in the concave section.

H. Markowitz has pointed out certain unusual implications of the Friedman-Savage hypothesis.[20] A person at the point M would take a fair bet with a chance to get to F. This seems unlikely to be verified by actual behavior. Secondly, if a person is at a position a little below F, he will not want insurance against small probabilities of large losses. Further, any person with income greater than F will never engage in any fair bet. But wealthy people do gamble. Is it solely the love of risk taking? To overcome these objections, Markowitz postulates that utility is related to *changes* in the level of income and that "the utility function has three inflection points. The middle one is at the person's "customary" income level, which except in cases of recent windfall gains and losses is the present income. The income interval between the inflection points is a nondecreasing function of income. The curve is monotonically increasing but bounded; it is at first concave, then convex, then concave, and finally convex.

Markowitz's hypothesis is consistent with the existence of both "fair" (or slightly "unfair") insurance and lotteries. The same individual will both insure and gamble. The hypothesis implies the same behavior whether one is poor or rich.

Markowitz recognizes that until an unambiguous procedure is discovered for determining when and to what extent current income deviates from customary income, the hypothesis will remain essentially nonverifiable because it is not capable of denying any observed behavior. The Markowitz hypothesis reveals perhaps more forcefully than the Friedman-Savage hypothesis, that utility has no meaning as an indicator of a level of utility. Utility has meaning only for changes in situations. Thus while I might choose to receive an increase in income rather than no increase, there is no implication that after I have received it for a while I remain on a higher utility base—however interpreted—than formerly. It may be the getting or losing, the rising or the falling that counts rather than the actual realized position. In any event Markowitz's hypothesis contains no implications about anything other than changes in income.

Our survey is now completed. We started with developments after

[20] H. Markowitz, "The Utility of Wealth," *Jour. Pol. Econ.* (April 1952), LX, 151-58.

the Slutsky, Hicks, Allen utility position in which utility is measured up to monotone transformations only. This meant exactly no more and no less than that utility is ordinal. In other words, the numerical size of the increments in the numbers in any one measure (column of numbers in Table I) is without meaning. Only their signs have significance. Utility translation: marginal utility has meaning only in being positive or negative, but the numerical value is meaningless, *i.e.*, *diminishing* or *increasing* marginal utility is completely arbitrary since one can get either by using the appropriate column.[21]

The first postwar development was the Neumann and Morgenstern axioms which implied measurable utility up to a linear transformation, thus reintroducing diminishing or increasing marginal utility,[22] and which also implied a hypothesis or maxim about rational behavior. This was followed by the Friedman and Savage article and Marschak's paper. These papers are essentially identical in their postulates and propositions although the presentation and exposition are so different that each contributes to an understanding of the other. The Friedman and Savage paper however contains an added element: they attempt to prophesy the shape of the curve of utility of income that would be most commonly revealed by this measurement process. Mosteller and Nogee then made a unique contribution in really trying to verify the validity and applicability of the postulates. Most recently, Markowitz criticized the Friedman and Savage conjecture about the shape of utility of income curve, with his own conjecture about its dependence upon income changes. And that is about where matters stand now.

A moral of our survey is that to say simply that something is, or is not, measurable is to say nothing. The relevant problems are: (1) can numerical values be associated with entities and then be combined according to some rules so as to predict choices in stipulated types of situations, and (2) what are the transformations that can be made upon the initially assigned set of numerical values without losing their predictive powers (validity)? As we have seen, the currently proposed axioms imply measurability up to a linear transformation. Choices among uncertain prospects are predicted by a simple probability-weighted sum of the utilities assigned to the components of the uncertain prospect, specifically from the "expected utility."

And now to provide emotional zest to the reader's intellectual activity the following test is offered. Imagine that today is your birth-

[21] It is a simple task—here left to the reader—to find current textbooks and articles—which will be left unnamed—stating that the indifference curve analysis dispenses with the concept of utility or marginal utility. Actually it dispenses only with *diminishing* or *increasing* marginal utility.

[22] Incidentally, the *Theory of Games* of Neumann and Morgenstern is completely independent of their utility discussion.

day; a friend presents you with a choice among three lotteries. Lottery A consists of a barrel of 2000 tickets of which 2 are marked $1000 and the rest are blanks. Lottery B consists of another barrel of 2000 tickets of which 20 are marked $100 and the rest are blanks. Lottery C consists of a barrel of 2000 tickets of which 1 is marked $1000 and 10 are marked $100. From the chosen barrel one ticket will be drawn at random and you will win the amount printed on the ticket. Which barrel would you choose? Remember there is no cost to you, this is a free gift opportunity. In barrel A the win of $1000 has probability .001 and the probability of getting nothing is .999; in barrel B the probability of winning $100 is .01 and getting nothing has probability .99; in barrel C $1000 has probability .0005, $100 has probability .005 and winning nothing has probability .9945. For each barrel the mathematical expectation is $1.00. The reader is urged to seriously consider and to make a choice. Only after making his choice should he read the footnote.[23]

Conclusion

1. Some readers may be jumping to the conclusion that we really can use *diminishing* or *increasing* marginal utility and that the "indifference curve" or "utility isoquant" technique has been superfluous after all. This is a dangerous conclusion. The "indifference curve" technique is more general in not requiring measurability of utility up to a linear transformation. But its greatest virtue is that unlike the earlier "partial" analysis of demand of a single commodity the indifference curve analysis by using an extra dimension facilitates intercommodity

[23] Only the reader who chose C should continue, for his choice has revealed irrationality or denial of the axioms. This can be shown easily. He states he prefers C to A and to B. First, suppose he is indifferent between A and B; he doesn't care whether his friend chooses to give him A or B just so long as he gets one or the other. Nor does he care how his friend decides which to give. In particular if his friend tosses a coin and gives A if heads come up, otherwise B, he is still indifferent. This being so, a 50-50 chance to get A or B is equivalent to C, as one can see by realizing that C is really equivalent to a .5 probability of getting A and a .5 probability of getting B. Thus if A and B are indifferent there is no reason for choosing C.

Second, the reader choosing C may have preferred A over B. We proceed as follows. Increase the prize in B until our new B, call it B′, is now indifferent with A. Form the uncertain prospect of A and B′ with probability of .5 for A. This is better than C since C is nothing but an uncertain prospect composed of A and the old B, with probability of .5 for A. Where does this leave us? This says that the new uncertain prospect must be preferred to C. But since the new uncertain prospect is composed of .5 probability for A and .5 for B′, the chooser of C must be indifferent between the uncertain prospect and A. (In axiom 3 let A and B be indifferent, and let C be identically the same thing as A. In other words, if the two entities in the uncertain prospect are equally preferred, then the uncertain prospect is indifferent to one of the entities with certainty.) The upshot is that A is just as desired as the new uncertain prospect which is better than C. Thus A is preferred to C, but the chooser of C denied this. Why? Either he understood and accepted the axioms and was irrational in making a snap judgment, or else he really did not accept the axioms. He may now privately choose his own escape. This example is due to Harry Markowitz.

analyses—the heart of price analyses. But does the more "precise" type of measurement give us more than the ordinal measurement gives? Yes. As we have seen, measurability "up to a linear transform" both implies and is implied by the possibility of predicting choices among uncertain prospects, the universal situation.

2. Nothing in the rehabilitation of measurable utility—or choice-indicating numbers—enables us to predict choices among groups of sure prospects. The "utility" of a group of sure prospects is not dependent on *only* the utility (assigned number) of the *entities* in the combination. It is dependent upon the particular *combination of entities; i.e.*, we do not postulate that the utility of one sure element in a group of sure things is independent of what other entities are included. We think it obviously would not lead to valid predictions of actual choices. Therefore, it must be realized that nothing said so far means that we could measure the total utility of a market basket of different entities by merely adding up the utilities of the individual component entities. No method for aggregating the utilities of the component entities for this purpose has been found; therefore, for this purpose we have to say that utility is not measurable.

3. Is the present discussion more appropriate for a journal in psychology or sociology? If economists analyze the behavior of a system of interacting individuals operating in field of action—called the economic sphere—by building up properties of the system from the behavior aspects of the individuals composing the system, then the economists must have some rationale of behavior applicable to the individuals. An alternative approach is to consider the whole system of individuals and detect predictable properties of the system. The classic example of this distinction is in physics. One approach postulates certain laws describing the behavior of individual molecules, or atom particles, while the other starts with laws describing the observable phenomena of masses of molecules. Apparently, most economists have relied upon the former approach, the building up from individuals—sometimes referred to as the aggregation of micro-economic analysis into macro-economic analysis. On the other hand, those who are skeptical of our ability to build from individual behavior find their haven in postulates describing mass behavior. The current utility analyses aid the former approach.

4. The expression "utility" is common in welfare theory. For demand theory and the theory of prediction of choices made by individuals, measurability of the quantity (called "utility") permits us to make verifiable statements about individual behavior, but there is as yet no such happy development in welfare theory. "Measurability up to a linear transformation" does not provide any theorems for welfare theory beyond those derivable from ordinality. I mention this in order to forestall temptations to assume the contrary. The social welfare

function as synthesized by Hicks and Scitovsky, for example, does not require the "utility" (choice-ordering numbers) of each individual to be measurable up to a linear transformation. It is sufficient that the individual's utility be measurable up to a monotone transformation—or, in other words, that it have merely ordinal properties. Ordinal utility is adequate in this case because orderings are made of positions or states in which, as between the two states compared, everyone is better off in one state than in the other. The welfare function does not enable a ranking of two states in one of which some people are worse off.[24] This would require an entirely different kind of measure of utility for each person because of the necessity of making interpersonal aggregations of utilities. As yet no one has proposed a social welfare function acceptable for this purpose, nor has anyone discovered how, even in principle, to measure utility beyond the linear transformation. Even more important, the various elements in the concept of welfare (as distinct from utility) have not been adequately specified. In effect the utility whose measurement is discussed in this paper has literally nothing to do with individual, social or group welfare, whatever the latter may be supposed to mean.

5. A brief obiter dictum on interpersonal utility comparisons may be appropriate. Sometimes it is said that interpersonal utility comparisons are possible since we are constantly declaring that individual A is better off than individual B. For example, "a rich man is better off than a poor man." But is this really an interpersonal utility comparison? Is it not rather a statement by the declarer that he would prefer to be in the rich man's position rather than in the poor man's? It does not say that the rich *man* is happier or has more "utility" than the poor *man*. Even if the rich man has a perpetual smile and declares himself to be truly happy and the poor man admits he is sorrowful, how do we know that the rich *man* is happier than the poor *man*, even though both men prefer being richer to being poorer? If I were able to experience the totality of the poor man's situation and the rich man's, and preferred the rich man's, it would not constitute an interpersonal comparison; rather it would be an *intrapersonal,* intersituation comparison.

It is hoped that the reader now has at his command enough familiarity with the meanings of measurability to be able to interpret and evaluate the blossoming literature on utility and welfare, and that this exposition has made it clear that welfare analysis gains nothing from the current utility analysis, and conversely.

[24] Absolutely nothing is implied about taxation. For example, justification of progressive income taxation by means of utility analysis remains impossible. The best demonstration of this is still E. D. Fagan, "Recent and Contemporary Theories of Progressive Taxation," *Jour. Pol. Econ.* (Aug. 1938), XLVI, 457-98.

DUTY AND NON-DUTY IMPORTS AND INCOME DISTRIBUTION

By ANTHONY Y. C. KOO*

The gains from international trade have long been of theoretical interest to economists. John Stuart Mill, "for the sake of simplicity," restricted his consideration of trade to two countries and two commodities. Alfred Marshall, in an elaboration of Mill's analysis, spoke of *E*'s (England's) and *G*'s (Germany's) goods as mutually exclusive categories of commodities conceptually gathered into "representative bales," the one traded against the other. For the purpose of exposition, Marshall designed the elegant and well-known reciprocal demand curves. Although F. D. Graham extended the analysis beyond the classical two-country-two-commodity case,[1] and thus rendered the two-dimensional Marshallian reciprocal demand curves inapplicable to his more than two-country-two-commodity cases, the Marshallian curves have continued to be used even in the most recent contributions in the field of tariff theory. Tariffs are assumed to be levied on the bales (which means on all types of imports) at a uniform rate, and little attention has as yet been paid to the more common and realistic mixed cases of duty and nonduty imports. This naturally raises the question of whether modifications of the existing theory of the effects of tariffs on income distribution are required if there are simultaneously both duty and nonduty imports.

Since the theory of duty and nonduty imports and income distribution which the writer attempts to present in this paper is a broadening of the results which Stolper and Samuelson[2] reached on the basis of the analysis of Heckscher and Ohlin[3] and which were later synthesized by Metzler,[4] it may be desirable to present a brief summary of the principal

* The author is assistant professor of economics at Michigan State College. He expresses indebtedness to Professors L. A. Metzler, L. S. Ritter, P. A. Samuelson, V. E. Smith and W. F. Stolper for comments on an earlier draft of this paper.

contributions to a subject which has not been developed until comparatively recent times.

I

The classical contribution with respect to the gains from international trade concerns the way in which the gains are divided among countries when each country is considered as a unit. Both the classical theory and its neoclassical refinements neglect to explore how the gains of real income from trade within each country are divided among the various factors of production.[5] The influence of international trade upon the distribution of national income did not receive much attention prior to Heckscher and Ohlin.

Heckscher began his discussion, as did the classical economists, by stating that trade between countries could be explained by the law of comparative costs. Unlike the classical economists, Heckscher emphasized that comparative costs differ between countries because the relative degree of scarcity of some factors of production differs between countries and because different commodities require varying proportions of the factors of production. Let us consider, for example, two countries, *E* and *G*. *E* has a large amount of land per worker as compared with *G*. Since it is to *E*'s advantage to use land to the point where its marginal product is relatively small, the ratio of rent to wage rates will then be lower in *E* than in *G*. Let us consider the comparative costs in *E* and *G* of producing two commodities, say, wheat and textiles. Since wheat requires a larger amount of land per worker than textiles do, *E* will have a comparative advantage in wheat while *G* will have a comparative advantage in textiles. *E* will then export wheat, and *G*, where rents are comparatively high and wages low, will export textiles. The exchange of goods will increase in each country the demand for factors of production in the export industry and reduce demand in those industries competing with imports; but, as Heckscher pointed out, the proportions in which factors of production are required in the export industry are not exactly the same as the proportions in which they are released by the industries competing with imports. In the present example, the shift of resources from textiles (the industry competing with imports) to wheat (the export industry) in *E* creates a relative scarcity of land in *E*, which before trade had a comparatively abundant supply. After trade, rent per unit of land rises in *E* relative to wages per unit of labor. An analogous argument could be presented to show that in *G*,

[5] In the English controversy over the corn laws, the question of income distribution was discussed. But the results of the controversy did not leave any permanent influence on the theory of international trade and, in this respect, were inconclusive. See C. F. Bastable, *The Theory of International Trade* (London, 1903), Ch. 6, as pointed out by Metzler, *ibid.*, p. 2.

which initially had a comparatively large supply of labor in relation to land before trade, there will be an increase of wage rates relative to rents after trade. Since international trade has a tendency to equalize relative and absolute factor returns among different countries, the owners of the relatively scarce factors of production would be interested in reducing the volume of trade to the extent that their losses as producers outweigh their gains from cheap imports, so that they can keep the relative scarcity which might otherwise be reduced by competition from abroad through trade.[6]

The clarification of this point constitutes the contribution of Stolper and Samuelson.[7] They showed that a country's scarce factor can be benefited by tariffs even though the national income may thereby be diminished. Their conclusion, however, was based on two main assumptions. The first is that there is only one import product, or that all import goods are measured in one common unit, and therefore a tariff could only cause factors of production to be shifted from the export industry to the industry competing with imports; and, according to the analysis of Heckscher and Ohlin, the export industry will be that which requires a comparatively small amount of the relatively scarce factor, and the industry competing with imports will be that which requires a large proportion of the scarce factor compared to other factors. The shift of resources brought about by the tariff leads to a net increment of demand over supply for the scarce factor and an excess supply of the other relatively abundant factors. Accordingly, the abundant factors can be absorbed only if the ratio of the scarce factor to the abundant factor is reduced. For this to occur, the marginal product of the scarce factor must increase in all industries.

The second assumption is that a country's external terms of trade are unaffected by the tariff. The tariff, in their argument, interferes with the allocation of resources without any offsetting favorable movement in the terms of trade.

The drawback of the Stolper-Samuelson paper, in making no allowances for changes in the terms of trade, was first pointed out by Metzler. "It is a curious fact that, just as the classical discussion of the terms of trade had neglected or left unsolved the related problem of the distribution of income, so the more recent contributions to the study of

[6] For a discussion whether international trade would achieve a complete or only a partial equalization of the relative and absolute factor returns in different countries, see P. A. Samuelson, "International Trade and Equalization of Factor Prices," *Econ. Jour.*, June 1948, LVIII, 163–86; "International Factor-price Equalization Once Again," *ibid.*, June 1949, LIX, 181–97. S. F. James and I. F. Pierce "The Factor Price Equalization Myth," *Rev. Econ. Stud.*, 1951–52, XIX (2), 111–20; P. A. Samuelson, "A Comment on Factor Price Equalization," *ibid.*, pp. 121–22.

[7] *Op. cit.*, pp. 333–57.

income distribution have neglected the complications arising out of changes in the terms of trade."[8] In view of this, Metzler synthesized the two branches of the subject and presented a refined version of the theory of tariff and income distribution. While he did away with the second restrictive assumption of Stolper and Samuelson, that of allowing for no change in the terms of trade, he still left untouched the first assumption of only one import product, because he carried out his argument by means of Marshallian reciprocal demand schedules. In a footnote, however, he mentioned that in adopting this method he had not added anything essentially new to the well-known classical technique. His purpose rather was to apply this technique to a problem which was seldom discussed and never strongly emphasized in classical literature.[9] Therefore Metzler's revised version of the theory still failed to take into account the more general case where there are duty and nonduty imports, although he suggested that a re-examination of his conclusions should be made for the case in which there are nonduty as well as duty imports.[10]

Metzler assumes that there are two countries, E and G. Country E exporbs b in exchange for a_{1g} from country G.[11] In Figure 1, the curves e and g represent the reciprocal demand schedules of the two countries, respectively, under conditions of free trade. Equilibrium is established at the point P, which implies that E imports an amount OT of a_{1g} in exchange for OW of b. Suppose country E imposes an *ad valorem* duty of 50 per cent upon imported a_{1g}. Let us neglect for the time being the effects of the spending of the proceeds of the tariff by the government of E. The tariff reduces the demand schedule facing the exporters of a_{1g} in G from e to e'. In other words, a_{1g} importers in E will now be willing to give to the exporters in G only TS units of b for OT units of a_{1g}. A money value of SP which citizens of E formerly gave to G would now go to the E government as duty. After the tariff, the new equilibrium in terms of quantities is at P', at which point OW' units of b are exported by E and OT' units of a_{1g} are imported. In Figure 1 the tariff improves the terms of trade of E. The fraction OT'/OW' is larger than OT/OW. This means that the world price of a_{1g}, exclusive of the tariff, has fallen relative to the world price of b. Such an improvement of the terms of trade is well known through the contributions of the classical theorists. In order to show how the tariff has affected the distribution of income in E, Metzler pointed out that the tariff must be added to

[8] *Op. cit.*, p. 2.

[9] *Op. cit.*, pp. 6–7.

[10] *Op. cit.*, pp. 21–22.

[11] I have changed the lettering of the Metzler diagrams as well as the names of commodities used in the illustration so that they will conform with the usage in Section II below.

the world price of a_{1g} measured in terms of E's export commodity. The total outlay of the residents of E for imported a_{1g} including their outlay for the tariff is now OW' in Figure 1 but OW'', an amount 50 per cent greater than OW'. The domestic ratio of exchange is, therefore, OT'/OW''. Since OT'/OW'' is less than OT/OW in Figure 1, the tariff has caused the domestic price of a_{1g} to rise relative to the price of b. The factors of production are therefore shifted to the domestic indus-

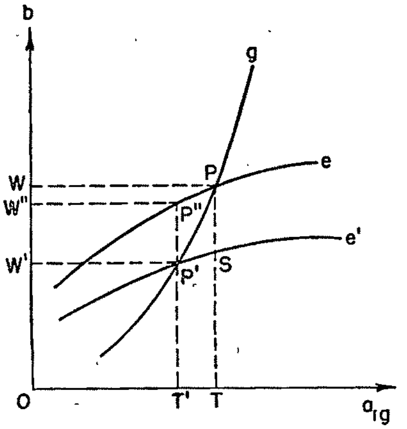

FIG. 1

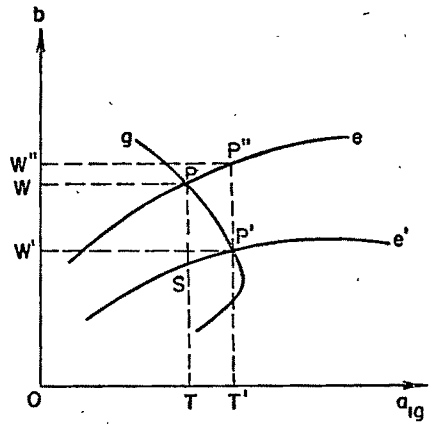

FIG. 2

try a_{1e} (competing with a_{1g}) from b (the export industry). Metzler then generalizes as follows:

> If the world demand for a country's exports is elastic and if we neglect the effects of government expenditures on the demand for imports, (1) a tariff always increases the domestic prices of imports relative to the prices of exports; (2) the improvement in the terms of trade is not sufficient, in this case, to offset the tariff itself; (3) the protected industries become more profitable, relative to the export industries; (4) resources are shifted from the latter to the former; and (5) the real returns to the country's scarce factors of production, as well as these factors' share in the national income, are increased. The Stolper-Samuelson conclusion is thus valid, even when changes in the terms of trade are taken into account, as long as the demand for exports is elastic.[12]

Then Metzler proceeds to the case in which the demand for exports is inelastic. In Figure 2, the demand of G for the products of E is assumed to be inelastic at the equilibrium point P. After the tariff is imposed, the point of balance of trade moves to P' at which point E gives up OW' units of b in exchange for OT' units of a_{1g}. As in the first case, the terms of trade move in favor of E. In fact, the favorable movement

[12] *Op. cit.*, p. 9.

in the terms of trade of E is now such that the domestic price of a_{1g}, including the tariff, is lower relative to the price of b than it was before the tariff was imposed, as is shown in Figure 2 by the fact that OT'/OW'' is greater than OT/OW. Thus when the demand for a country's exports is inelastic, a tariff on a_{1g} reduces the domestic price of a_{1g} relative to the price of b and leads to a shift of resources in E from a_{1e} (the domestic industry competing with a_{1g}) to b (the export industry). The scarce factors of production and the industries competing with imports under this condition actually achieve economic gains from free trade and suf-

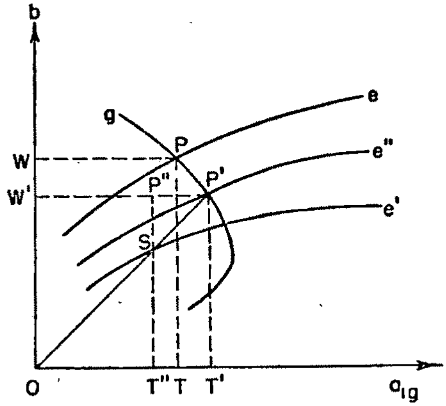

FIG. 3

fer losses under protection. Therefore in this case the Stolper-Samuelson conclusions are invalid.

Next, Metzler makes it clear that the way in which a government imposing the import duty disposes of the resultant revenue would affect the income distribution. In Figures 1 and 2, it is assumed that no part of the tariff proceeds is spent on imported goods. If it were, the reciprocal demand would not fall by the full amount of the tariff as shown in the figures. So Metzler next assumes an extreme case in which customs revenues are used entirely in the purchase of imports. This case is represented by Figure 3. As in the earlier diagrams, equilibrium is initially at P. A tariff is imposed upon a_{1g} imports into E, but the entire proceeds are now assumed to be spent upon a_{1g}. The additional demand of the government for imports prevents the demand schedule of E for the products of G from falling as far as it otherwise would have fallen. In Figure 3, the new demand schedule, including the government's demand for imports, is shown by line e''. The private demand schedule not including the government's demand is line e'.[13] As in the earlier

[13] For a discussion of the relations between the three demand schedules, e, e', and e'' and the procedure by which e'' is to be derived from e and e', see Metzler, *op. cit.*, pp. 11–12.

examples, the tariff improves the terms of trade of country E, which means that the price of E's imports, exclusive of the tariff, declines relative to that country's exports. OT/OW is greater than OT'/OW'. These terms of trade are, however, measured in world prices, and, as before, it is the domestic price ratio rather than the world price ratio which governs the distribution of income in the duty-imposing country. As far as the residents of E are concerned, the domestic ratio of exchange is given by the point P''. They would purchase OT'' units of a_{1g} for which they would pay $T''S$ units of b to country G, and an additional SP'' units of b to their government. Since P'' lies to the left of P, it represents a higher domestic price of a_{1g}, including the tariff, relative to the price of b, than does the point P. The amount of duty SP'', in the present example, is assumed to be spent entirely on a_{1g} at the world ratio of exchange between b and a_{1g}, exclusive of the tariff. The ratio, for purposes of illustration, was assumed by Metzler to be represented by the slope of the line OSP' (Fig. 3). E's government would get $P''P'$ amount of a_{1g} and pay SP'' in terms of b.

Consequently, when the proceeds of the tariff are spent entirely on imports, as shown in Figure 3, the direct influence of the tariff toward raising the price of a_{1g} in E is more important than the indirect influence toward improving that country's terms of trade. The net effect is an increase of the domestic price of a_{1g}, including the duty, relative to b, even though the foreign demand for the exports of the duty-imposing country is inelastic. The tariff, accordingly, leads to a shift of resources from the export industry b to a_{1e} (the domestic industry competing with a_{1g}). Therefore when customs duties are used entirely in the purchase of imports, no modifications are required in the Stopler-Samuelson conclusion. And this would be true regardless of the size of the elasticity of demand for the duty-imposing country's exports.

In the foregoing discussion Metzler considers two extreme cases in which: (1) the demand for E's exports is inelastic and the proceeds of the tariff are spent *entirely* on the export good, with the result that the domestic price including the tariff would go down; and (2) the demand for E's exports is inelastic and the proceeds of the tariff are spent *entirely* for imports, with the result that the domestic price of a_{1g}, including the tariff, would go up. Between these extremes Metzler finds an intermediate case in which the proceeds are assumed to be divided between the purchase of imports and exports respectively. In such case the domestic price of a_{1g}, including the tariff, might remain the same as the world price.[14] In other words, the relative prices actually paid and re-

[14] For an exact statement of the conditions under which the forces affecting domestic prices will cancel each other, see L. A. Metzler, "Tariffs, International Demand and Domestic Prices," *Jour. Pol. Econ.* (Aug. 1949), LVII, 345–51.

ceived by consumers and producers of the two goods b and a_{1e} (competing with a_{1g}) may be unaltered by the tariff. No shift in resources between the two industries would take place and the distribution of income would be the same as before the tariff was imposed. Metzler's result depends upon the balance between two forces working in opposite directions. On the one hand, the tariff would cause a direct increase in the prices of imports, relative to the prices of exports. On the other hand, the tariff reduces the demand for imports, and, unless the country imposing the duties is small, this reduction in demand is likely to reduce the world prices of such imports relative to the prices of the country's exports. If the first of the opposing influences dominates, the domestic prices of imports, including the tariff, will go up relative to the prices of exports. If the second of the opposing influences dominates, the domestic prices of imports, including the tariff, will go down relative to the prices of exports. If one just counterbalances the other, the domestic prices of imports, including the tariff, will remain unchanged. Whether one or the other of these opposing forces will dominate depends upon conditions of foreign demand for the duty-imposing country's exports, and upon the way in which the tariffs affect the demand for imports.

> If the world's demand for exports of the tariff-imposing country is elastic or if the tariffs do not reduce the demand for imports at home to any substantial degree, the movement of world prices is likely to be negligible. The final effect will therefore be an increase in the domestic prices of imports, including the tariffs, relative to the prices of the country's exports. But if the world demand for the tariff-imposing country's exports is inelastic and if the tariffs reduce the demand for imports in the tariff-imposing country to a considerable extent, the fall in world prices of imports, relative to world prices of exports, may be so large that domestic prices of imports are relatively lower than before the tariffs were imposed, even after the tariffs are added to the world prices.[15]

By way of summary, let us tabulate the effects of tariffs on income distribution, after taking into account the changes in the terms of trade as done by Metzler; then we shall examine the validity of the Stolper-Samuelson results as modified by Metzler, with duty as well as nonduty imports.

II

In order to show the effects of duty and nonduty imports on income distribution, let us assume three commodities, a_1, a_2, and b.

	Domestic Commodities			*Export Commodities*	
Country E...........	a_{1e}		a_{2e}		b
Country G...........		b		a_{1g}	a_{2g}

[15] *Ibid.*, p. 345.

TABLE I.—METZLER'S RESULTS

	Case	A. World demand for E's (the duty-imposing country) exports is elastic	B. World demand for E's (the duty-imposing country) exports is inelastic
1.	Proceeds of duty used entirely to purchase E's export commodities	X	Y
2.	Proceeds of duty used entirely to purchase E's imports	X	X
3.	Proceeds of duty divided between E's exports and imports	X	Indeterminate; X, Y, Z, cases are all possible

X. The domestic prices of imports, including the tariff, will go up in E (the duty-imposing country). The Stolper-Samuelson results are valid, namely that the scarce factor of the country can benefit by means of tariffs.

Y. The domestic prices of imports, including the tariff, will go down in E. The Stopler-Samuelsön results become invalid.

Z. The domestic prices of imports, including the tariff, will remain unchanged in E. The Stolper-Samuelson results become invalid.

Assume that the export industry b in E requires a large amount of the relatively abundant factors and the domestic industries are those which require a small proportion of the abundant factors compared to other factors. Within the domestic industries a_{1e} and a_{2e} in E, the respective requirements for the abundant and the scarce factors may differ. For instance, a_{1e} may require a comparatively smaller amount of abundant factors in relation to scarce factors than a_{2e}, or *vice versa*. If labor (L) be the scarce factor and capital (C) the abundant factor, we have the following possible ratios between labor and capital in the domestic industries in E:[16]

$$\left(\frac{L_1}{C_1}\right)_{a_{1e}} \gtreqless \left(\frac{L_1}{C_2}\right)_{a_{2e}} > \left(\frac{L_b}{C_b}\right)_b.$$

[16] The relationship between total labor and total capital to L_1/C_1, L_2/C_2 and L_3/C_3 is as follows:

Since total capital $C = C_1+C_2+C_3$
and total labor $L=L_1+L_2+L_3$

$$\text{it follows that } \frac{\text{total labor}}{\text{total capital}} = W_1\frac{L_1}{C_1}+W_2\frac{L_2}{C_2}+W_3\frac{L_3}{C_3}$$

$$W_1=\frac{C_1}{C};\ W_2=\frac{C_2}{C};\ W_3=\frac{C_3}{C} \qquad W_1=1-(W_2+W_3)$$

See P. A. Samuelson, "International Trade and Equalization of Factor Prices," *loc. cit.*, p. 174, and Stolper and Samuelson, *op. cit.*, pp. 349–51.

Pure competition in the factor and product markets, a constant (inelastic) supply of factors of production, and perfect domestic mobility of factors of production are assumed throughout. In each country there exist demand functions for each of the commodities. Equilibrium requires that price ratios be such as to equate the demand and supply of the two countries taken together for each commodity.

Let us draw in Figure 4 country E's production opportunity surface

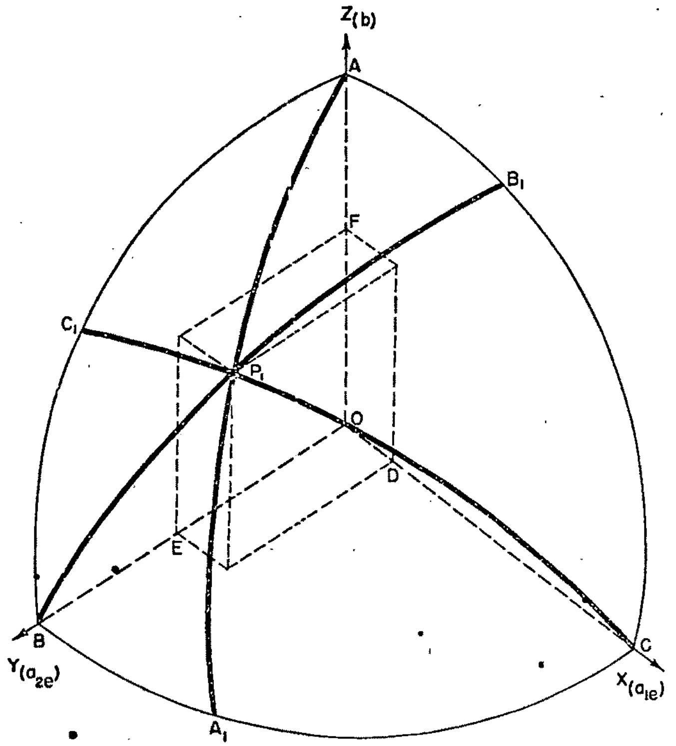

FIG. 4

of commodities a_{1e}, a_{2e} and b ($[f(a_{1e}, a_{2e}, b] = 0$ in the first quadrant) which represents the maximum combinations of a_{1e}, a_{2e}, and b that can be produced. Quantities of a_{1e} are measured along the X-axis, quantities of a_{2e} along the Y-axis and quantities of b up the Z-axis so that any point in the space among the three axes represents a certain combination of a_{1e}, a_{2e}, and b. In the two-commodity case, the production opportunity surface becomes the familiar production opportunity curve. If the entire available supply of factors of production is employed in producing a_{1e}, it can produce OC. If employed entirely to produce a_{2e}, it can produce the quantity OB, and if employed entirely in producing b, it can produce the quantity OA. For every unit of a_{1e} by which production is

reduced, more a_{2e} and/or b can be produced. Thus, all the possible combinations of a_{1e}, a_{2e}, and b which can be produced by utilizing all the available factors of production lie upon the surface. The surface is drawn concave towards the origin, signifying increasing opportunity cost. Because proportions and not the scale of the process are involved, the production functions are assumed to be homogenous of the first order. Since the relative costs—the substitution ratios—will vary with the relative demand for a_{1e}, a_{2e}, and b, given the combinations of a_{1e}, a_{2e}, and b which are demanded, the exchange ratios between them will equal their substitution ratios at the equilibrium point.[17] In diagrammatic language, the above statement means that at the point of equilibrium the market plane must be tangent to the production opportunity surface. (The market plane is not shown in Figure 4.) The change or lack of change of relative output and, accordingly, relative prices, between any pair of the commodities, is shown by the surface lines through the vertices of the production opportunity surface. For example, the line AA_1 represents the constant relative output between a_{1e} and a_{2e}. Similarly, the surface line BB_1 indicates the constant relative output between a_{1e} and b. Inasmuch as any change of relative outputs among the three commodities would be in accordance with the changes of relative prices, henceforth we shall simply indicate the change of relative prices of the three commodities by referring to the appropriate changes in the line on the production surface.

III

Let us assume that country E exports b in exchange for a_{1g} and a_{2g}, and equilibrium is established under the conditions of free trade at P_1 on the production opportunity surface in Figure 4. Let us project P_1 onto the planes AOB, AOC, and BOC, respectively. Output would be OD of a_{1e}, OE of a_{2e}, and OF of b before the imposition of duty on a_{1g} by country E. Suppose that country E imposes an *ad valorem* duty on imports of a_{1g} class commodities and no duty is levied on a_{2g} class commodities. Let us assume that country G, the exporter of a_{1g}, does not choose to retaliate.[18] It is clear that the effect of the tariff is a reduction of the demand schedule facing the producers of a_{1g} class commodities in G, because a part of the money value which residents of E formerly gave to G now goes to the E government as duty.

What is the effect of the duty on the domestic price of a_{1g} in the duty-

[17] The assumptions under which the exchange and transformation ratios will be identical are competition, indifference of factors with respect to the industry in which they are employed, and absence of external economies and diseconomies. See G. Haberler, "Some Problems in the Pure Theory of International Trade," *Econ. Jour.* (June, 1950), LX, 225.

[18] Tibor de Scitovszky, "A Reconsideration of the Theory of Tariffs," *Readings in the Theory of International Trade*, pp. 358–89.

imposing country *E*? It is known that the world price of a_{1g}, exclusive of the tariff, will fall in terms of b unless E is a very small buyer of a_{1g}. But in terms of domestic prices, the tariff must be added to the world price of a_{1g}, and this would cause the domestic price of a_{1g} in E to rise relative to b. This statement is valid whether the proceeds of the duty are used entirely to purchase *E*'s exports (Metzler's case 1A in Table I), or used to purchase *E*'s imports (Case 2A), or are divided between

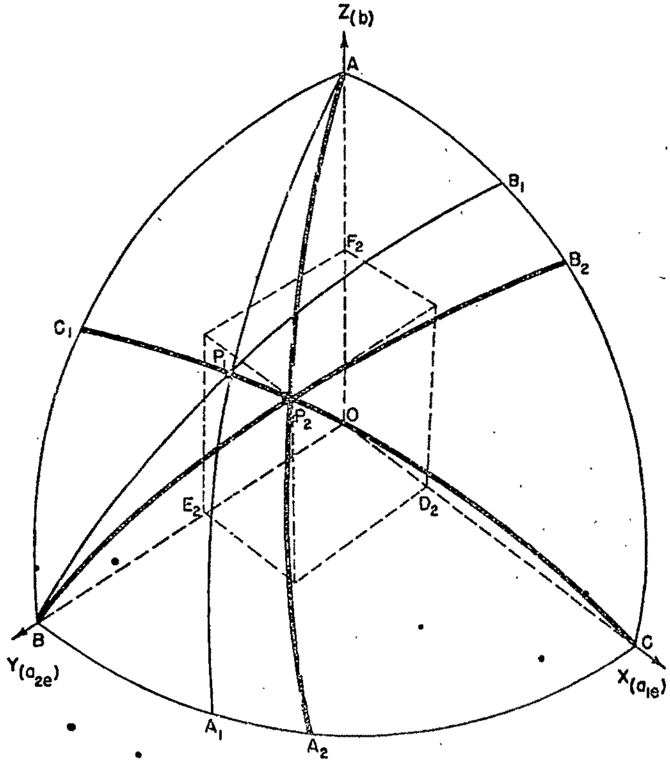

FIG. 5

E's exports and imports (Case 3A). Therefore, in the two-commodity case, as Stolper-Samuelson and Metzler all agree, the factors of production are to be shifted from b, the export industry, to a_{1e}, the domestic industry in E. Since $(L_1/C_1)_{a_{1e}} > (L_b/C_b)_b$ in the present illustration, the scarce factor of production, namely, labor, will benefit. But in three-commodity cases, a change of relative price between a_{1e} and b, as shown in Figure 5, also means a change of relative price between a_{2e} relative to a_{1e} and/or b.[19] This is the familiar proposition that the structure of

[19] For a mathematical demonstration of this point, see the appendix.

our economic system determines the relative prices of all commodities. In this particular case, the prices of commodities a_{1e} and a_{2e} are expressed in terms of b.

Before determining whether a tariff on a_{1g} class of imports and none on others would affect income distribution, we have to know not only the relative pride change between duty imports, including the tariff, and exports but also the relative price change between nonduty imports and exports.[20] Since the price of the duty imports, including the tariff, is bound to go up relative to b with the elastic foreign demand for E's exports (Metzler's Cases 1A, 2A and 3A), the three possible cases of price movements of nonduty imports will be examined.

CASE 1. *The price of nonduty imports remains unchanged.* In Figure 5, the increase in the domestic price of a_{1g} (and accordingly the price of a_{1e} competing with a_{1g}) in E, including the tariff, relative to b is represented by the shift of the surface line from BB_1 to BB_2. Since there are three commodities, the change of relative price between a_{1e} and b automatically means a change of the relative price between a_{1e} and a_{2e}. This is represented by the shift of the surface line from AA_1 to AA_2. The surface line CC_1 remains unchanged. The new equilibrium position accordingly moves from P_1 to P_2 in Figure 5 where the market plane is again tangent to the production surface[21] (not shown in the figure). Projecting P_2 onto the three planes respectively, output would be OD_2 of a_{1e}, OE_2 of a_{2e} and OF_2 of b. Since $OD_2 > OD$, $OE_2 < OE$, and $OF_2 < OF$, the expansion of the protected industry is at the expense of both a_{2e} (the domestic industry) and b (the export industry). This proves that Stolper-Samuelson and Metzler conclusions, though interesting, are valid only under the two-commodity case where the price of a_{1e} (competing with a_{1g}) can increase only relative to b (the exports of E). Therefore, the expansion of the protected domestic industry requiring a large proportion of scarce factors compared to other factors can only be at the expense of the export industry requiring a comparatively small amount of scarce factors in relation to other factors. Once the expansion of the protected industry can draw in the factors of production released by export and domestic industries, the effect of the tariff on income distribution within the duty-imposing country depends upon the ratio between the scarce and the abundant factors required in the respective domestic industries. If the protected industry a_{1e} makes greater or equal relative use of the scarce factor than the domestic industry a_{2e} competing with nonduty imports, or, $(L_1/C_1)_{a_{1e}} \geqq (L_2/C_2)_{a_{2e}}$, then for every unit

[20] Since there is no duty on a_{2g}, its domestic price in E is assumed to be identical to the world price.

[21] The change of price ratio between a_{1e} and b as well as between a_{1e} and a_{2e} can be expressed by the slopes of the tangent planes at $P_1[(\partial a_1/\partial a_2)_{P_1}$ and $(\partial a_1/\partial b)_{P_1}]$ which are different from the slopes of the tangent plane at $P_2[(\partial a_1/\partial a_2)_{P_2}$ and $(\partial a_1/\partial b)_{P_2}]$.

of labor (L), the scarce factor, transferred from the export industry and the domestic industry competing with nonduty imports to the protected industry, a larger amount of capital (C), the abundant factor, will be released than the protected industry will absorb. Hence labor (L) becomes scarcer. Only then can one claim that a tariff on a_{1e} will benefit the scarce factor. Uncertainty about the outcome arises if the protected industry a_{1e} is the one which makes relatively less use of labor (L) than the domestic industry a_{2e} competing with nonduty imports, or,

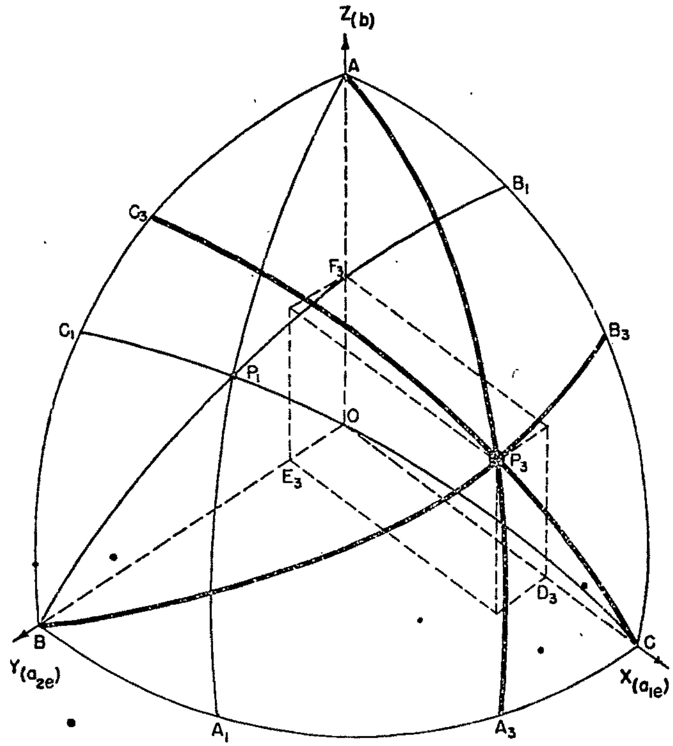

FIG. 6

$(L_1/C_1)_{a_{1e}} < (L_2/C_2)_{a_{2e}}$. In so far as factors are released by the export industry, labor (L) becomes scarcer as $(L_1/C_1)_{a_{1e}}$ or $(L_2/C_2)_{a_{2e}}$ is always greater than $(L_b/C_b)_b$; but in so far as factors are drawn from a_{2e} with $(L_1/C_1)_{a_{1e}} < (L_2/C_2)_{a_{2e}}$, ($L$) becomes less scarce. The net result is thus uncertain.

CASE 2. *The price of nonduty imports goes down.* Next we shall examine the case where the domestic price of a_{1g} (and, accordingly, the price of a_{1e} competing with a_{1g}) goes up relative to b while the price of a_{2g} (and accordingly the price of a_{2e} competing with a_{2g}) goes down relative to b. In Figure 6, the former price shift is shown by the movement of the sur-

face line from BB_1 to BB_3, the latter by the change of CC_1 to CC_3. Since the prices of a_{1e} and a_{2e} move in opposite directions with respect to b, the relative price between a_{1e} and a_{2e} must also move as represented by the shift of the surface line AA_1 to AA_3. This means the domestic price of a_{1g} (and, accordingly, the price of a_{1e} competing with a_{1g}), including the tariff, will be higher relative to b which in turn will be higher relative to a_{2e}. Or, in other words, the domestic price of a_{1g}, including the tariff, will be higher relative to both b and a_{2e}. The equilibrium point as a result of such price changes moves from P_1, the initial point of equilibrium under free trade, to P_3. Project P_3 onto the planes AOB, AOC, and BOC respectively, output would be OD_3 of a_{1e}, OE_3 of a_{2e}, and OF_3 of b. Since $OD_3 > OD$, $OE_3 < OE$, and $OF_3 < OF$, the expansion of a_{1e} will be at the expense of both a_{2e}, the domestic industry, and b, the export industry, and no generalization can be drawn under the circumstances concerning the effect of the tariff on income distribution, if $(L_1/C_1)_{a_{1e}} < (L_2/C_2)_{a_{2e}}$. If, on the other hand, the protected industry a_{1e} makes greater or equal relative use of the scarce factor than the domestic industry a_{2e}, competing with nonduty imports, or, $(L_1/C_1)_{a_{1e}} \geqq (L_2/C_2)_{a_{2e}}$, then a tariff on a_{1e} will benefit labor (L), the scarce factor.

CASE 3. *The price of nonduty imports goes up.* The last possible case is one in which the prices of both a_{1g}, including the tariff, and a_{2g} increase relative to b. In order to examine the effect of a tariff on income distribution in this case, see Figure 7. The former price increase is represented by the shift of the surface line from BB_1 to BB_4, and the latter price increase by the shift of the surface line from CC_1 to CC_4. The new point of equilibrium moves from P_1 to P_4. Project P_4 onto the planes AOB, AOC, and BOC respectively. Output would be OD_4 of a_{1e}, OE_4 of a_{2e}, and OF_4 of b. Since $OD_4 > OD$, $OE_4 > OE$, and $OF_4 < OF$, the expansion of both a_{1e} and a_{2e} (both domestic industries) would be at the expense of b (the export industry) *alone*. In such a case our conclusion agrees with the one reached by Stolper-Samuelson and Metzler irrespective of the fact that $(C_1/L_1)_{a_{1e}} \gtreqless (C_1/L_1)_{a_{2e}}$.

Let us summarize our conclusions in this section. When the foreign demand for the duty-imposing country E's exports is elastic, the domestic price of the duty import goes up. The effect of a tariff on income distribution would then depend upon what happens to the price of a_{2g}, and whether or not the relative use of the scarce factor by the protected industry a_{1e} is more or less than, or equal to, that in the domestic industry a_{2e} competing with nonduty imports. If the price of a_{2g} remains unchanged or decreases relative to b, and if the protected industry a_{1e} makes greater or equal relative use of the scarce factor than the domestic industry a_{2e} competing with nonduty imports, or, $(L_1/C_1)_{a_{1e}} \geqq (L_2/C_2)_{a_{2e}}$, then a tariff on a_{1e} will benefit the scarce factor. This is

trade. Suppose that an *ad valorem* duty is imposed on imports of class a_{1g} commodities and no duty on a_{2g} class commodities. As before, the terms of trade between a_{1g} and b move in favor of E. In fact, the favorable movement in the terms of trade may now be so great that the domestic price of a_{1g}, including the tariff, will be lower relative to b than it was before the tariff was imposed, if the proceeds of the duty are used entirely to purchase E's exports (Metzler's Case 1B). The domestic

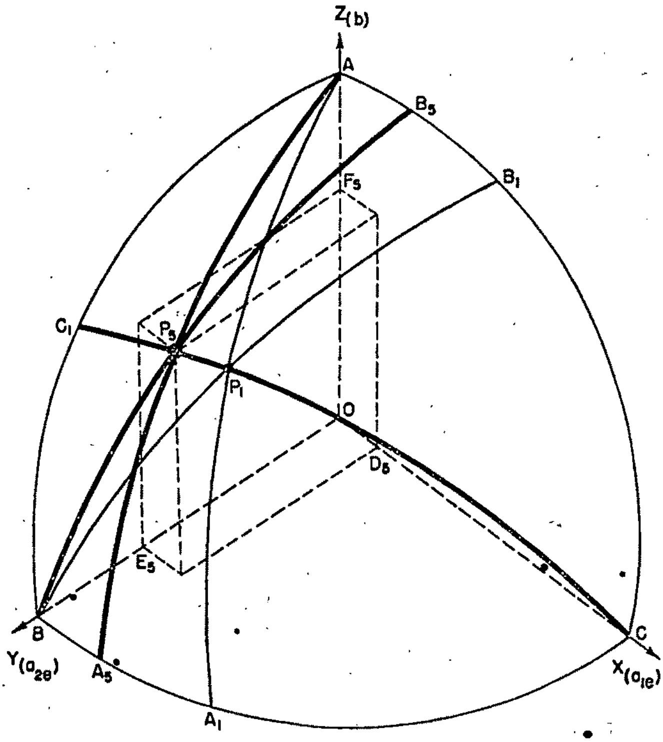

FIG. 8

price of duty imports a_{1g}, including the tariff, may, however, go up if the proceeds of the duty are used entirely to purchase E's imports (Case 2B); and finally, it may remain unchanged if the proceeds are divided in a certain way between E's exports and imports (Case 3Z). Since the effect upon income distribution cannot be determined without knowing also the direction of the price change in nonduty imports in E, and since the price of nonduty imports may go up, down or remain unchanged, there are three cases corresponding to the three possible price movements of duty imports.

CASE 4. *Price of duty imports goes down while the price of nonduty im-*

ports remains unchanged. In Figure 8, before the imposition of tariff, the initial position of equilibrium is P_1. A decrease of price of a_{1g} (and accordingly the price of a_{1e} competing with a_{1g}) including the tariff, relative to b means a shifting of the surface line BB_1 to BB_5. Assume that there is no change of relative price between a_{2e} and b. Since all three commodities are expressed in terms of relative prices, a change of the price between a_{1e} and b with no change of price between a_{2e} and b must mean a change of the relative price between a_{1e} and a_{2e}. This is represented by the shifting of the line AA_1 to AA_5 in Figure 8. Consequently, the relative outputs of all three commodities are affected. The new point of equilibrium is now P_5. Project P_5 onto the planes AOB, AOC, and BOC respectively. The output of a_{1e} is OD_5, of a_{2e}, OE_5, of b, OF_5. Since $OD_5<OD$, $OE_5>OE$, and $OF_5>OF$, the factors released by a_{1e} are absorbed by both domestic and export industries and the effect of a tariff on income distribution depends upon the ratio between the scarce and the abundant factors required in the respective domestic industries. If $(L_1/C_1)_{a_{1e}} \geqq (L_2/C_2)_{a_{2e}}$: then for every unit of capital (C), the abundant factor, transferred, a larger number of units of labor (L), the scarce factor, will be released than the domestic industry competing with nonduty imports and the export industry will absorb. Hence L becomes less scarce. The effect of a tariff will thus be unfavorable to the scarce factor. However, uncertainty about the outcome arises if $(L_1/C_1)_{a_{1e}}<(L_2/C_2)_{a_{2e}}$. In so far as factors are absorbed by the export industry, L becomes less scarce, but in so far as factors are absorbed by a_{2e} with $(L_1/C_1)_{a_{1e}}<(L_2/C_2)_{a_{2e}}$, L becomes scarcer. The net result is uncertain.

CASE 5. *Price of duty imports goes down while the price of nonduty imports goes up.* Next we shall consider the case where the domestic price of a_{1g}, including the tariff, (and accordingly the price of a_{1e} competing with a_{1g}), goes down relative to b, and the price of a_{2g} goes up relative to b. In Figure 9, the former price change is represented by the shift of the surface line from BB_1 to BB_6 and the latter change by the shift of line CC_1 to CC_6. Since the prices of a_{1e} and a_{2e} move in opposite directions with respect to b, the relative price between a_{1e} and a_{2e} must also move as represented by the shift of the surface line AA_1 to AA_6. Or, in other words, the domestic price of a_{1g}, including the tariff, is lower relative to both a_{2e} and b. As a result of the relative price changes, the point of equilibrium moves from P_1 to P_6. Project P_6 onto the planes AOB, AOC and BOC, respectively. The output of a_{1e} is OD_6, of a_{2e}, OE_6, and of b, OF_6. Since $OD_6<OD$, $OE_6>OE$, and $OF_6<OF$, the expansion of a_{2e} would be at the expense of both a_{1e}, the domestic industry, and b, the export industry. Again, the *a priori* conclusion concerning the effect of the tariff on income distribution de-

pends upon whether the relative use of the scarce factor by the protected industry a_{1e} is more or less than, or equal to, that by the domestic industry a_{2e} competing with nonduty imports. If $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$ the outcome is uncertain. If, on the other hand, $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$ the effect of a tariff on income distribution would be favorable to the scarce factor.

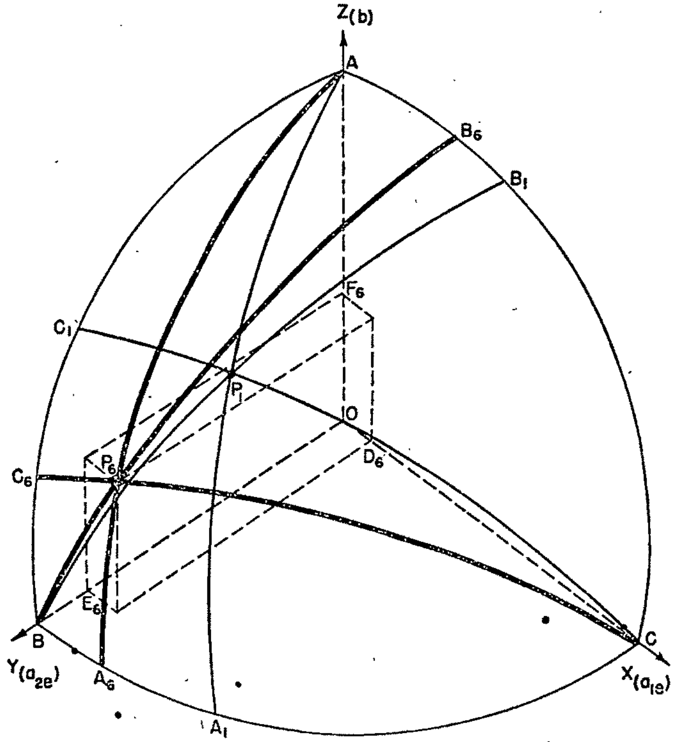

FIG. 9

CASE 6. *Price of nonduty import goes down while the price of duty imports also goes down.* This case concerns a decrease of the domestic price of a_{1g} (and accordingly the price of a_{1e} competing with a_{1g}), including the tariff, in E relative to b coupled with a decrease of the price of a_{2g} (and accordingly the price of a_{2e} competing with a_{2g}) also relative to b. The former price change is represented by the shift of the surface line from BB_1 to BB_7 in Figure 10 and the latter, by the shift of CC to CC_7. Consequently, the point of equilibrium moves from P_1 to P_7 Project P_7 onto the planes AOB, AOC and BOC, respectively. OD_7 of a_{1e}, OE_7 of a_{2e} and OF_7 of b are produced. Since $OD_7 < OD$, $OE_7 < OE$ and $OF_7 > OF$, the expansion of b, the export industry, in E is at the expense of a_{1e} and a_{2e}, both domestic industries. Thus Metzler's result

that when the demand for the duty-imposing country's exports is inelastic, the scarce factors of production and the industries competing with imports might achieve economic gains under free trade and suffer losses under protection (Case 1B) is compatible with our analysis even with the presence of nonduty imports as long as the price of nonduty imports also goes down relative to b. This result is true whether the relative use of the scarce factor by the protected industry a_{1e} is more or

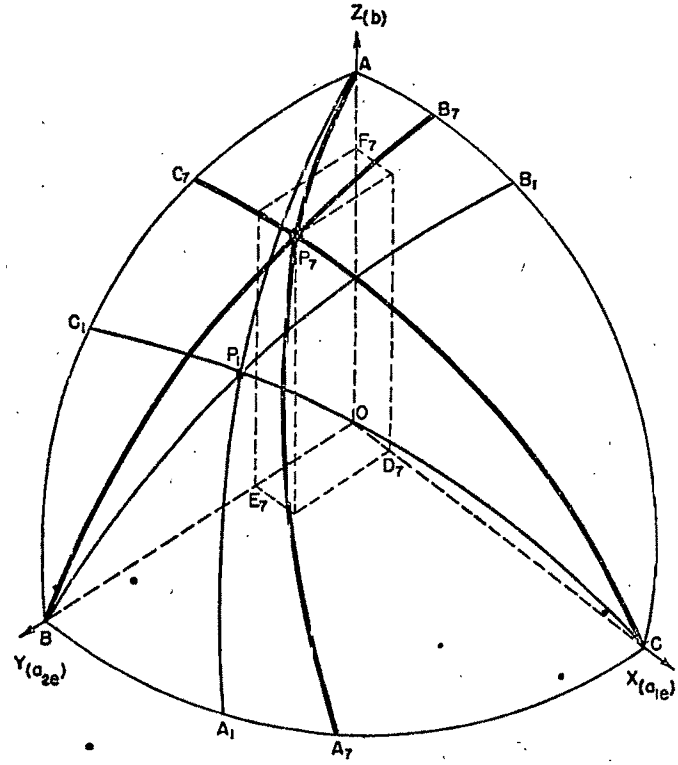

FIG. 10

less than, or equal to, that by the domestic industry a_{2e} competing with nonduty imports.

As regards Metzler's Case 2B, namely, that in which the price of duty imports, including the tariff, may go up when the proceeds of the duty are spent entirely on imports even though the foreign demand for E's exports may be inelastic, there are also three possible cases of price movements of a_{2g} to consider. Inasmuch as their effects are analogous to Cases 1 to 3 considered in the preceding section, we may go on to the case where the domestic price of a_{1g}, including the tariff, may remain unchanged (Metzler's Case 3Z). Again there are three possible cases of price movement of a_{2g} to consider.

CASE 7. *The prices of duty and nonduty imports remain unchanged relative to b.* If the prices of b, a_{1g}, and a_{2g} remain unchanged, then AA_1, BB_1 and CC_1 would also remain unchanged and P_1 in Figure 4 would still be the equilibrium point on the production surface. This means that there will be no change of relative outputs following the tariff on a_{1e} in the duty-imposing country E and thus no change in income distribution.

CASE 8. *The price of duty imports remains unchanged and the price of nonduty imports rises.* On the basis of analysis in the previous sections, when the price of one of the domestic industries goes up relative to b, while the price of the other remains unchanged, also relative to b, the expansion of a_{2e} in the present case would be at the expense of the other domestic industry a_{1e} and the export industry. The effect of the tariff in E on income distribution depends upon whether the relative use of the scarce factor by the protected industry is more or less than, or equal to, that by the domestic industry a_{2e} competing with nonduty imports. Uncertainty arises if $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$. If, on the other hand, $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$, the effect of a tariff on income distribution would be favorable to the scarce factor.

CASE 9. *The price of duty imports remains unchanged and the price of nonduty imports falls.* We know that under such circumstances, the factors of production released by the domestic industry a_{2e} competing with the nonduty imports may be absorbed both by the export industry b and the other domestic industry a_{1e}. Again the result on income distribution is uncertain if $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$, and unfavorable to the scarce factor if $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$.

To sum up the analysis in this section, when the foreign demand for exports of the duty-imposing country E is inelastic, the domestic price of duty imports, including the tariff, may go up, go down, or remain unchanged relative to b. In the first group of cases where a_{1g} goes up relative to b we have exactly the same results as when the foreign demand for E's exports is elastic. In the second group of cases where the price of a_{1g} goes down, the effect on income distribution depends upon the price of nonduty imports. If the price of a_{2g} goes up or remains unchanged relative to b, the effect on income distribution becomes also dependent upon whether the relative use of the scarce factor by the protected industry a_{1e} is more or less than, or equal to, that by the other domestic industry a_{2e} competing with nonduty imports a_{2g}. In the case where the price of a_{2g} goes up the effect of a tariff on income distribution will be favorable to the scarce factor if $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$. However, uncertainty arises if $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$. In the case where the price of a_{2g} remains unchanged, the effect of a duty on income distribution will be unfavorable to the scarce factor if

$(L_1/C_1)_{a_{1e}} \geqq (L_2/C_2)_{a_{2e}}$ and the result will be uncertain if $(L_1/C_1)_{a_{1e}} < (L_2/C_2)_{a_{2e}}$. If the price of a_{2g} goes down relative to b, then the expansion of b would be at the expense of both domestic industries and the effect of the duty on income distribution would be unfavorable to the scarce factor. The last group of cases is that in which the domestic price of a_{1g}, including the tariff, may not change. If the price of a_{2g} also remains unchanged, a tariff on a_{1g} has no effect on income distribution. In the case where there is an increase of the price of a_{2g}, the result on income distribution will be indefinite if $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$, and favorable to the scarce factor if $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$. In the case in which there is a decrease of the price of a_{2g}, the result is uncertain if $(L_1/C_1)_{a_{1e}} > (L_2/C_2)_{a_{2e}}$, and unfavorable to the scarce factor if $(L_1/C_1)_{a_{1e}} \leqq (L_2/C_2)_{a_{2e}}$.

V

A summary of the conclusions of this paper is given in Table II. We find that in the framework of three commodities, the Samuelson-Stolper results, as amended by Metzler, imply the assumption that in

the duty-imposing country the domestic price of duty imports, including the tariff, must move in the same direction as the domestic price of nonduty imports. That is to say, when the former price goes up or down or remains unchanged relative to that of the export industry, the latter must also go up or down or remain unchanged relative to that of the export industry. This restrictive assumption underlying their analysis is not noticeable under the two-commodity case, because there are no nonduty imports in their system. When the price change of nonduty imports does not move in the same direction as that of duty imports, the factors of production can thus be transferred to the protected industry from both the domestic industry competing with nonduty imports and the export industry. Since the ratios of the scarce factor of protection to the abundant factor within the domestic industries may differ, the effect of a tariff on income distribution also becomes dependent upon whether the relative use of the scarce factor by the protected industry is more or less than, or equal to, that in the domestic industry competing with nonduty imports. Thus the price of nonduty imports and the relative use of the scarce factor within the domestic industries must be included among those data necessary for determining the effect of a tariff on income distribution.[22]

Mathematical Appendix

In general, the points where coordinates satisfy the relation $f(x, y, z)=0$ lie upon a surface and we say that the equation (in the first quadrant) represents this surface (Figure 4). Through P_1 pass a plane, include z-axis, and cut the surface curve at points AP_1A_1. The curve AP_1A_1 on this surface can be expressed in the equation:

$$y = k_1x. \tag{1}$$

To reduce the space equation to a line equation, we rewrite (1)

$$\frac{y}{x} = k_1. \tag{2}$$

Likewise pass a plane through P_1, include y-axis, and cut the space curve at BP_1B_1, thus

$$z = k_2x$$

or

$$\frac{z}{x} = k_2. \tag{3}$$

[22] This analysis still leaves many questions unanswered. Among them is the question as to the effects on income distribution of the imposition of a duty in cases involving relationships between complementary and substitution goods and means of production and finished goods, but the limitation of space does not permit the writer to consider such cases.

Similarly, pass a plane through P_1, include x-axis, and cut the space curve at CP_1C_1, thus

$$y = k_3 z$$

or

$$\frac{y}{z} = k_3. \tag{4}$$

Substitute x of (1) into (3)

$$\frac{y}{k_1} = \frac{z}{k_2}$$

or

$$\frac{y}{z} = \frac{k_1}{k_2} = k_3. \tag{5}$$

This means that if we shift one plane (surface curve), we should also change the other plane or planes so that the ratio $k_1/k_2 = k_3$ can be maintained.

We can prove our case with the use of the formula of a market plane tangent to the surface at the point P.

$$z - z_1 = \left(\frac{\partial z}{\partial x}\right)_p (x - x_1) + \left(\frac{\partial z}{\partial y}\right)_p (y - y_1).$$

If we let $z - z_1 = \Delta z$, $x - x_1 = \Delta x$, and $y - y_1 = \Delta y$, we have.

$$\Delta z = \frac{\partial z}{\partial x}\Delta x + \frac{\partial z}{\partial y}\Delta y.$$

Let us divide the above equation through by Δx and the limit taken as $\Delta x \to 0$ and then by Δy and the limit taken as $\Delta y \to 0$. The results are

$$\frac{dz}{dx} = \frac{\partial z}{\partial x} + \frac{\partial z}{\partial y}\frac{dy}{dx} \tag{6}$$

$$\frac{dz}{dy} = \frac{\partial z}{\partial x}\frac{dx}{dy} + \frac{\partial z}{\partial y}. \tag{7}$$

By similar reasoning,

$$x - x_1 = \left(\frac{\partial x}{\partial y}\right)_p (y - y_1) + \left(\frac{\partial x}{\partial z}\right)_p (z - z_1)$$

$$\Delta x = \frac{\partial x}{\partial y}\Delta y + \frac{\partial x}{\partial z}\Delta z$$

$$\frac{dx}{dy} = \frac{\partial x}{\partial y} + \frac{\partial x}{\partial z}\frac{dz}{dy} \tag{8}$$

$$\frac{dx}{dz} = \frac{\partial x}{\partial y}\frac{dy}{dx} + \frac{\partial x}{\partial z} \tag{9}$$

also

$$y - y_1 = \left(\frac{\partial y}{\partial x}\right)_p (x - x_1) + \left(\frac{\partial y}{\partial z}\right)_p (z - z_1)$$

$$\Delta y = \frac{\partial y}{\partial x}\Delta x + \frac{\partial y}{\partial z}\Delta z$$

$$\frac{dy}{dx} = \frac{\partial y}{\partial x} + \frac{\partial y}{\partial z}\frac{dz}{dx} \tag{10}$$

$$\frac{dy}{dz} = \frac{\partial y}{\partial x}\frac{dx}{dz} + \frac{\partial y}{\partial z}. \tag{11}$$

This means when a change of price of x as compared with y or z following a tariff occurs, a change of the relative prices and accordingly outputs of x, z, and y is bound to follow if the equality signs in (6), (7), (8), (9), (10), and (11) are to be maintained.

EXCESS LIQUIDITY AND EUROPEAN MONETARY REFORMS, 1944-1952

By John G. Gurley*

During the early postwar years in this country, there was much discussion concerning the probable effects of large liquid asset holdings on consumption and private investment spendings. Some economists, reasoning along strictly Keynesian lines, visualized these assets as influencing private spending only through changes in the interest rate. Many others, however, felt that excess liquidity would have a *direct* inflationary effect on the spending habits of both households and business firms. Nevertheless, few economists at this time were willing to argue that the conventional anti-inflationary measures were either unworkable or unfeasible in the face of so much excess liquidity. What was needed to turn aside the forces of inflation, it was argued, was a substantial government surplus[1] coupled with tight credit controls; many also urged the continuance of direct controls over prices and wages until these forces had subsided. The existence of excess liquidity was largely taken for granted with the result that, except for a few digressions, the discussion centered around the question of how inflationary these holdings would be and not around the question of how to rid the economy of them.

However, in many areas of Europe at this time, the second question commanded more interest than the first, primarily because it was generally agreed that there was imminent danger of hyperinflation if the volume of liquid assets were not drastically reduced.[2] Further, a wide-

* The author is assistant professor of economics at Princeton University. He is indebted to W. J Baumol, E. O. Edwards, and P. J. Strayer, all of whom offered valuable comments on earlier drafts. He also wishes to acknowledge the aid received in Europe during the summer of 1951 as a result of discussions with numerous individuals, too many to be listed here. The study was made possible by a grant from the Merrill Foundation, which the author gratefully acknowledges.

[1] Actually, of course, if one is free to alter both government expenditures and tax rates, there are many government deficits that would be just as deflationary as any given surplus.

[2] The difference in attitude between U.S. and many European economists on this question was due partly to the fact that the liquid asset-national income ratio was substantially higher in most European countries than it was in the United States after the war. However, whatever this ratio, quantity theorists tended to stress more vigorously the direct inflationary threat of these assets than did Keynesian theorists. In this connection it is interesting to note that where Keynesian doctrine in Europe was particularly strong—in England and the Scandinavian countries—either no steps to reduce excess liquidity were undertaken or else only token gestures in this direction were made.

spread feeling existed that if the assets were allowed to remain in the system they would undermine any monetary-fiscal program aimed at deflation. Through European eyes, the presence of large liquid asset holdings created a serious stumbling block in the path leading to inflation control. As a consequence, one of the principal anti-inflationary weapons used in this area of the world was monetary reform[3] which, in one way or another, swept away large portions of liquid assets accumulated by the public in the course of war and occupation. Many of these programs were designed to slow down the course of inflation and to prepare the way for the utilization of more orthodox anti-inflationary programs.

A study of the European monetary reforms, therefore, should throw some light on the broad topic of "the economics of excessively liquid economies." In this paper it is the intention of the author to consider: (1) the various ways in which the large liquid holdings of the European population were swept away, (2) the factors that induced many European countries to center their attacks on these holdings, (3) the degree of success attained by the programs, and (4) the conditions under which the monetary reform became a necessary part of any broad anti-inflationary program. It is hoped that this study will focus the attention of economists on a relatively neglected aspect of anti-inflationary policy, and that it will prove useful in further analysis of the rôle of liquidity.

I. *The Extent and Nature of the European Monetary Reforms*

The monetary reform was used widely throughout Europe during the post-World War II period. In fact, several countries in eastern Europe[4] relied upon this monetary device more than once, the most recent repeat performances taking place in Poland (October 1950), Rumania (January 1952), and Bulgaria (May 1952).

It was, however, a western European country, Belgium, which opened the attack on inflation in this manner by introducing a monetary reform program as early as October 1944, several months before the fighting within her borders terminated. Within a year, four other western European nations had followed suit, and these reforms were matched, or were soon to be matched, by a host of similar measures elsewhere.[5] Altogether, there were twenty-four monetary reforms in

[3] The expression, "monetary reform," has been used in the literature to describe a variety of monetary and banking programs. In this paper, however, it refers to those particular measures that reduced, or partially blocked for periods ranging from a few days to several years, the large liquid asset holdings of households and businesses.

[4] For the purposes of this paper, eastern Europe includes Finland, Greece, and all European countries (including the USSR) which now have communist governments.

[5] As we shall see, though, some of these programs were not designed primarily as anti-inflationary weapons.

Europe from the fall of 1944 to mid-1952. Some countries, such as Great Britain, Sweden, and Italy, did not utilize this technique at all; the majority employed it only once during the early years of the post-war period; and several, as mentioned above, used it two or three times.

The monetary reform, at one extreme, swept away the major portion of liquid holdings during the first few days of the program. At the other extreme, no reduction in the supply of liquid assets took place; instead, a small portion of the assets was blocked for a short period of time and then released to its owners. Inasmuch as the liquid assets affected by the programs generally comprised only banknotes and bank deposits—sometimes government and other securities were included—the monetary reform was at times similar to a capital levy applied to an extremely narrow base. It was a once-and-for-all "tax" on claims to wealth; however, in most cases no tax receipts accrued to the State, since the face values of the assets were written down, and to this extent a portion of the assets completely disappeared from the economy. When the assets were blocked (and not swept away), the reform was a "forced asset-holding" scheme, analogous to a program of forced saving out of current income. Finally, it was a "reform" in the sense that new banknotes were always issued for the old ones; in some instances, the unit of account was changed along with the entire price and wage structures.

II. *The Principal Types and Provisions of European Monetary Reforms*

Despite the almost endless array of provisions contained in the monetary laws, it is possible to group these programs into three general types, based on the manner in which the various countries dealt with the excessive supply of liquid assets in their economies. There were, first, those monetary reforms that reduced the supply of liquid assets at the outset without blocking any portion of this supply. This "mopping-up" operation was accomplished through the compulsory exchange of old banknotes and "old" bank deposits for new ones at rates of exchange which effectively reduced the outstanding volume of these assets. Each family and business firm was permitted to exchange its holdings of banknotes and deposits for new ones at the established conversion rate, say, three-to-one as in the 1947 Austrian program. Occasionally, however, some basic amount was allowed exchange rights at par, and other par exchanges were sometimes made for emergency cases or for favored groups. Once these exchanges were consummated, though, the program's initial objective was realized: individuals and businesses owned a smaller volume of liquid assets, but they were free to spend whatever remained.

The second type of monetary reform embodied no immediate reduc-

tion in the supply of liquid assets, but instead provided for the immobilization of a portion of this supply in the form of blocked deposits at banks. Again, banknotes were called in and bank deposits were declared by their owners during a specified period of time. In this case, each family and business firm was permitted to convert its old assets for new ones at a one-to-one ratio, but only a certain amount of new money was turned over to it for free use. The "excess assets" were placed in special bank accounts which in general could not be drawn upon for the purchase of current goods and services. In short, individuals and businesses retained in full their prereform holdings of these assets, since these holdings were all converted at par, but they were permitted to spend only a certain portion of them.

The third type combined the primary features of the other two. Currency and bank deposits were, first of all, converted into new money at deflated rates of exchange, but a portion of the amount remaining was in turn frozen in blocked accounts. One thousand units of a currency, for example, would be exchanged for five hundred new units, and, of this amount, two hundred and fifty of the new units would be tied up in accounts not usable for current transactions.

In all three types, the monetary provisions often called for the registration of securities, life insurance policies, personal property, and other forms of wealth. The authorities' primary interest in doing this was to survey the distribution of these holdings for the purpose of later capital levies or capital increment taxes. Only occasionally was the supply of financial assets, other than currency and deposits, reduced or partially blocked. In a few cases, though, government bonds were converted at deflated rates, and in one instance the public debt was cancelled by the monetary law.

Using the above classification as a guide, Table I lists the European monetary reforms in chronological order and classifies each as either Type One, Two, or Three. Since a series of two or even three reforms occurred in some of the countries, the successive reforms for any one of these countries are identified with Roman numerals after the name of the country.

The table records twenty-four separate monetary reforms from October 1944 to May 1952. Of this total, eight were of Type one, twelve of Type Two, and only four of Type Three. One-half of the reforms were introduced before the end of 1945, and since mid-1948 there have been only three reforms, all of them taking place in eastern Europe. Further, of the last seven reforms, five were undertaken in eastern Europe and only two—those of West Germany and France—occurred in west European locales.[6] The countries of western Europe

[6] The French program involved no more than a temporary blocking of the 5,000 franc banknotes.

TABLE I.—CLASSIFICATION OF EUROPEAN MONETARY REFORMS

Country	Month and Year of Reform	Types		
		One	Two	Three

[a] The Polish reform was carried out in three phases. In the first, ruble banknotes were exchanged at par for new zloty notes (December 1944); in the second, Cracow zloty notes were exchanged for new zloty notes (January 1945); and in the third, reichsmark notes were converted (February 1945).

[b] The initial Austrian reform was applicable only to those areas of the country occupied by the Soviet army.

[c] However, the Dutch called in and blocked 100 guilder banknotes in July 1945.

[d] The provisions of this program also affected deposits blocked under the previous two programs.

that made use of the monetary reform, with two exceptions, employed the Type Two program. Although a sprinkling of eastern European countries also resorted to this type, for the most part Types One and Three prevailed in this sector of Europe.

The Type One Reform

The Type One reform was first introduced in Greece in late 1944 when that country was in the midst of hyperinflation. About a year later, Hungary adopted the same type of reform to reduce her banknote circulation, and after this failed to halt inflation she repeated the pro-

gram, this time in a more vigorous and comprehensive fashion, and was successful. Shortly after this, Austria and the USSR undertook to dampen inflationary pressures with this type of program, the latter setting the pattern for the 1950 Polish, and the 1952 Rumanian and Bulgarian reforms. The prevalence of the Type One reform is largely explained by the attempts of two countries (Greece and Hungary) to stabilize economies plagued with hyperinflation, and by the desire (or necessity) of several Soviet-bloc countries to imitate the principal features of the USSR program of December 1947.[7]

Although each of these eight reforms provided for a reduction in the supply of liquid assets at the outset, without the utilization of blocking techniques, there were still many differences among their provisions.

TABLE II.—PRINCIPAL PROVISIONS OF TYPE ONE REFORMS

Country	Rates of Exchange	
	Banknotes	Bank Deposits
Greece	50 billion=1	50 billion=1
Hungary I	4=1	
Hungary II	200 million=1[a]	200 million=1[a]
Austria III	3=1	3=1
USSR	10=1	1=1; 3=2; 2=1[b]
Poland II	100=1	100=3[c]
Rumania II	100=1; 200=1; 300=1; 400=1[d]	50=1; 100=1; 150=1; 200=1[d]
Bulgaria II	100=1	4=1 to 200=1[e]

[a] This is in terms of the tax-pengoe. In terms of the so-called flat pengoe, the rate of exchange was 400 octillion-to-one!

[b] Rates applied to following ranges: 0–3,000; 3,001–10,000; over 10,000 rubles.

[c] Presumably only savings deposits were accorded this rate.

[d] Rates applied to following ranges: 0–1,000; 1,001–2,000; 2,001–3,000; and over 3,000 lei.

[e] The most favorable rates were accorded to savings deposits, deposits of private enterprises not exceeding the amount of the wage bill for the last month, and deposits of state and co-operative enterprises, offices, organizations, and foreign representatives. Other deposits were exchanged at either 100- or 200-to-one.

The principal differences were revealed in (1) the rates of exchange employed between old and new money, (2) the exchange rights accorded to holders of various types of liquid assets, (3) the exchange

[7] It probably would have been impossible for the Greeks and Hungarians to have stabilized their soaring price levels by means of temporary blocking techniques. What was needed, along monetary reform lines, was a fresh start, *i.e.*, a drastic reduction of the means of payment and a complete revamping of the price and wage structures.

Why the USSR chose the Type One reform is not altogether clear. P. A. Baran suggested that the administrative work connected with a blocking program would have been too formidable, and that, anyway, the peasants might not have tolerated such measures. See Baran, "Currency Reform in the USSR," *Harvard Bus. Rev.*, Mar. 1948, XXVI, 205. It is also true, however, that this type of reform had been used in the USSR in 1923. In the official text of the 1947 monetary law, the Soviets mentioned this precedent with much pride.

rights granted to owners of differing amounts of liquid assets, and (4) the rates of exchange applied on the basis of the identity of the owner himself. Table II records the provisions which reflect most of these differences.

The exchange rates employed in the reforms varied all the way from one-to-one (applied only to small deposits) in the USSR to 50 billion-to-one in the Greek reform.[8] The first Hungarian program contained a ratio between old and new banknotes of four-to-one, but in the second reform the rate of 200 million-to-one was adopted (or, 400 octillion-to-one in terms of the flat pengoe), reflecting the degree of inflation which had taken place in that country between the last month of 1945 and mid-1946.[9] In the USSR, the conversion rates ran from one-to-one to ten-to-one, while in the 1950 Polish program they reached 100-to-one, and in the Bulgarian (II)[10] and Rumanian (II) reforms, 200-to-one and 400-to-one, respectively.[11] In almost all cases, coins and small denomination banknotes were exempted from the conversion laws.

Not only were there wide differences among the conversion rates used by these countries, but distinctions were sometimes made on the basis of the type of liquid asset owned by the family or business firm. Thus, the Soviet Union "taxed" all banknotes at ten-to-one, but permitted bank deposits more favorable treatment. The same procedure was adopted in the Rumanian (II) reform in which bank deposits were hit only half as hard as comparable holdings of banknotes. The provisions of the Hungarian (I) reform affected only banknotes, leaving bank deposits untouched, while in Poland (II) and Bulgaria (II) savings deposits were highly favored over banknote holdings. These provisions were sometimes used to strike particularly hard at a certain group known to be in possession of a large volume of one type of asset—such as the banknote-holding peasants in the USSR—or to discourage black

market activities usually engaged in with large denomination banknotes, or, finally, to encourage the depositing of currency in savings deposits for the purpose of decreasing the velocity of circulation.

The third distinction was based on the amount of liquid assets owned by individuals and business firms. While, as mentioned above, the Soviets gave more favorable treatment to bank deposits than to banknotes, they also favored small holders of these deposits over large holders. In Rumania (II), small holders of either banknotes or deposits were favored over large holders, the rates ranging from 100-to-one to 400-to-one for banknotes, and from 50-to-one to 200-to-one for bank deposits. Apparently, owners of small savings deposits in Bulgaria (II) also received special treatment. The progressive rates employed by these reforms were largely designed to bring about a more equal distribution of liquid assets, to hit certain capitalist elements with particular severity, or to achieve other social goals.

Finally, the fourth distinction was based on the identification of the owner of the assets. Thus, in Bulgaria (II) all deposits held by private businesses were converted at the highly unfavorable rate of 200-to-one. The Austrian (III) reform granted special treatment to farmers so far as their banknote holdings were concerned and small depositors were hit lightly.[12] In some cases, deposits owned by governmental units, financial institutions, and charitable and religious organizations were either exempted or treated in a special manner.

In most of the Type One reforms, not only were "excess assets" swept away, but also large portions of transactions balances, at pre-reform price and wage levels, were eliminated by the monetary provisions. Whenever this occurred, it was necessary for the authorities to lower the price and wage structures in their economies to fit the new, lower level of liquid assets (money supply). Thus, a reduction of liquid assets in the ratio of 50- or 100-to-one did not mean that the *real* value of these assets was reduced to that extent, since prices and wage-rates were lowered simultaneously. Several countries chose this course because their pre-reform inflated price and wage levels were already far out of line with others, and because such a course seemed to offer the best method for "breaking the back" of the inflationary spiral.

In the Bulgarian (II) reform, for example, the *average* conversion rate for liquid assets was about 100 old leva for 2.4 new leva, while most prices and wage-rates were converted in the ratio of 100-to-four. The same reduction in the real value of liquid assets could have been achieved if the assets had been converted in the ratio of 100 old leva

[12] For the main outlines of the Austrian reform, see F. H. Klopstock, "Monetary and Fiscal Policy in Post-Liberation Austria," *Pol. Sci. Quart.* (Mar. 1948), LXIII, 122-23.

for 60 new leva, with prices and wage-rates remaining unchanged. The Hungarians (II) also revamped their price and wage structures, and in Rumania (II) these "flow magnitudes" were lowered by about 80 per cent at the time of the monetary reform. On the other hand, the Austrians (III) and the Hungarians (I) converted prices and wages at par, while in the USSR wages and other regular payments were converted at par, but the price system was unified and a general lowering of the price level occurred.

The Type Two Reform

The Belgians were the first to experiment with the Type Two monetary reform, the main features of which were copied several months later by Denmark, the Netherlands, Norway, and Czechoslovakia.[13] Both Finland and France (II)[14] utilized this technique for the temporary blocking of banknotes, and a few of the eastern European countries, before they became allied with the Soviet orbit, introduced reform measures of this type.

There were generally three phases to this type of monetary reform. First, the major portion of banknotes and bank deposits was blocked during the initial days of the program. Second, certain basic allotments and releases were made to individuals and business firms so that normal economic activity might continue. Third, the funds, or part of them, which remained blocked after the primary releases were consummated were gradually deblocked either through individual requests to a deblocking committee, through blanket releases that spanned all deposits, or by other means.

Within this framework, however, each country went about the tasks of first immobilizing and then demobilizing a portion of the liquid asset supply in its own way. In some cases, the formulas chosen were quite simple, but in other instances they were so complex as to defy under-

[13] Descriptions of these programs are found in V. A. deRidder, "The Belgian Monetary Reform," *Rev. Econ. Stud.*, 1947-48, XV (2), 51-69; *idem*, "The Belgian Monetary Reform: An Appraisal of the Results," *ibid.*, 1948-49, XVI (1), 25-40; *Reports and Accounts*, Danmark Nationalbank, 1945, pp. 30-34; *White Paper Regarding the Measures for the Currency Rehabilitation in the Netherlands* (The Hague, 1947); *De Nederlandsche Bank Report for 1946* (Amsterdam, 1947), p. 27, and same *Reports* for later years; Kaare Peterson, "The Monetary Reconstruction Program in Norway," *Norwegian American Commerce*, Feb. 1946, XI, 3-21; and *National Bank of Czechoslovakia Bulletin*, Mar.-Apr. 1948, pp. 1-5 in annex.

standing by the majority of the population; moreover, some of the programs were dragged out for several years after their introduction.[14a] A few of the Type Two reforms initiated in 1945 were still in the process of liquidation as late as the winter of 1951.

The provisions making up the first phase of these reforms varied somewhat from country to country. In most cases, though, the reforms exempted coins, small denomination banknotes, and certain deposits from the initial blocking regulations. The primary reason for exempting coins and small notes was to reduce the volume of administrative work during the currency exchange period. The exempted bank deposits generally included those held by financial institutions, governmental units, other public or semipublic bodies, and charitable and religious organizations. In these cases, all other bank deposits, together with the larger denomination banknotes, were placed in blocked accounts. However, some programs were quite limited in scope. For example, Finland's law hit only 500, 1,000 and 5,000 mark banknotes, leaving the smaller notes and all bank deposits untouched. In France (II), only 5,000 franc notes were subject to the blocking provisions, while the first Austrian reform blocked only bank deposits. In the majority of cases, though, large portions of the liquid asset supplies came under the blocking regulations.

In the second phase of the programs, the basic allotments and releases of funds were made on several bases: (1) per capita; (2) the average monthly wage bills of employers; (3) the date on which the deposit was first opened; (4) the type of liquid asset owned; and (5) the amount of liquid assets owned. The per capita allotments were made so that consumers would have enough to live on until their next pay checks. The releases to employers enabled the flow of wage and salary payments to be resumed. Finally, the partial deblocking of deposits was oftentimes accomplished on discriminatory bases—favoring all deposits opened before the outbreak of war ("good deposits"), treating more harshly those opened during the occupation ("bad deposits"), in a

[14a] The provisions in the Netherlands and Austria were so involved as to be almost beyond imagination. One need only mention that during the life of the Dutch program—it lasted for over six years—there were free deposits, clearing accounts, blocked accounts, option accounts, investment accounts, and several other forms under which funds were tied up. In Austria, after the appearance of the second reform in 1945, there were six different types of deposits in existence. The distinctions were based on the zone in which the individual resided, the date the bank deposit was opened, and the reform under which the deposit was regulated. By the time the third reform came along—the provisions of which cancelled outright some deposits, converted others on a deflated basis, left others untouched, converted a few into forced loans, and blocked still others for a short period of time and the remainder for longer periods—the average depositor was sorely pressed to determine what he fully, only partially, or did not own. The Belgian program also became tangled in many complications, and in Czechoslovakia a Currency Liquidation Fund had to be introduced to administer the final stages of that program.

few cases favoring savings deposits over other types of asset holdings, and usually granting somewhat larger percentage releases to owners of small holdings than to the wealthier owners.

The third and final phase of these reforms—the gradual deblocking of all, or part of, the immobilized funds—was pursued with some marked differences from country to country. These differences were revealed in (1) the methods used to deblock funds, (2) the percentage of funds ultimately returned to their owners, and (3) the rapidity with which the funds were returned. We will briefly consider each of these.

There were generally four types of releases made: (a) releases, on special request, to individuals who had been especially hard hit financially by the war and occupation, or to invalids, oldsters and others; (b) releases for the payment of taxes, the purchase of government bonds, and in some instances for the purchase of insurance policies and other financial and real assets; (c) automatic blanket releases after a specified period of time had elapsed; and (d) discretionary blanket releases in the light of the economic situation as it developed month by month. Many countries relied upon all four methods of releasing funds, but even in these cases the emphasis was often quite different.

There were also differences with respect to the percentage of blocked accounts ultimately released to their owners. In a few instances, all, or almost all, of the blocked funds were returned. This was true in France (I and II), Denmark, Norway, and Finland. In other countries, large portions of these funds were wiped out in one way or another in the later stages of the programs, and in these cases the reforms were, in effect, similar to the Type One programs, in which the total supply of liquid assets was reduced at the outset. In Belgium, for example, after the initial allotments were made, the authorities segregated all blocked deposits into two categories: temporarily blocked deposits (40 per cent of the total), and permanently blocked deposits (60 per cent of the total). The latter portion was largely eliminated by the conversion of these deposits into forced loans and the subsequent redemption of the loan certificates with funds derived from special capital levies. To some extent, this path was also followed in the Netherlands, Czechoslovakia, and Bulgaria (I). In one country, Austria, the authorities simply cancelled a portion of the blocked deposits.

Finally, of the funds ultimately released, a major portion of them was released in a few days or weeks in some countries, while in others the programs continued for years. In France (I) the funds were released almost immediately, in France (II) and Denmark, after only a few months, and in Belgium, the Netherlands, and Norway, only after several years. The percentage of funds released and the rapidity with which they were released depended primarily upon the objectives of the programs. Whenever the principal objective was to contain inflation,

the funds were usually deblocked slowly and then only in part. In other cases, the bulk of them was released rapidly.

The Type Two programs were, on the whole, quite different from the Type One reforms with respect to their treatment of prices and wages. In the former, the flow magnitudes of the economy were generally left unchanged, while in the latter, as we have seen, they were often drastically altered. The primary purpose of the authorities in carrying out many of the Type Two reforms was simply to skim off the excess liquidity, at prereform prices and wages. Thus, although the average Norwegian had less liquid assets after monetary reform than he had before, the prices he paid for consumer goods and the wages he received were approximately the same a week after the reform as they had been just prior to it.

The Type Three Reform

Enough has been said above to make it unnecessary to delve deeply into the provisions of the Type Three monetary reform, inasmuch as these programs incorporated the principal features of the other two types. In this set of reforms, the liquid asset supply was reduced at the outset by the application of deflated rates of exchange to old currency and deposit holdings, but, in addition, a portion of the remaining supply was frozen in blocked accounts.

The reform carried out in West Germany in 1948 offers a typical example of the measures to be found in this hybrid type of program.[15] In that country, all banknotes were called in and bank deposits were declared between June 20 and 26. Each person then received 60 new deutschemark notes (DM) for 600 old reichsmark notes (RM). Employers were presented with 60 DM per employee for 600 RM.[16] Most bank deposits were converted at the same rate—10 RM for 1 DM—and one-half of the resulting DM balances was freed and the other half blocked. During October 1948, 70 per cent of the blocked balances were cancelled, 20 per cent were transferred to a free account; and 10 per cent were made available for investment in certain securities to be specified later.

The Soviet-sponsored reform in East Germany was quite similar to the program conducted in the western zones.[17] One difference, however,

[15] There is a wealth of material available on this reform. See, for instance, F. A. Lutz, "The German Currency Reform and the Revival of the German Economy," *Economica*, May 1949, XVI, 122-42, and H. Mendershausen, "Prices, Money and the Distribution of Goods in Postwar Germany," *Am. Econ. Rev.*, June 1949, XXXIX, 646-72.

[16] It was at first believed that the initial per capita and employee allotments were made at par. The actual rate of exchange was not made apparent until a week later.

[17] See, Haut-Commissariat de la Republique Française en Allemagne, *Étude d'Ensemble sur la Situation Economique et Financière de la Zone Soviètique d'Occupation en Allemagne de 1945 à 1950* (Berlin, Mar. 31, 1950).

was that savings deposits were converted at differential rates: one-to-one for the first 100 marks, five-to-one for the next 900, and ten-to-one for all in excess of 1,000 marks. The first Rumanian reform was also patterned along these lines, except that the amount of the initial allotment was more dependent on the economic class in which the individual found himself.[18] For example, farmers were highly favored as to the amount of banknotes that they could exchange for new ones. On the other hand, unemployed persons, military personnel, and individuals in work camps and prisons were permitted to exchange substantially smaller sums. Moreover, certain commercial firms were granted no conversion rights at all. The exchanges were made at the rate of 20,000-to-one, and, in addition, a portion of the new funds was blocked and only gradually released in the later stages of the program.

The monetary reform in West Germany was accompanied by a general decontrol of prices and wages, while in Rumania (I) the price and wage structures were completely revised and lowered. East Germany and Yugoslavia apparently maintained the flow magnitudes at approximately the same levels and kept them under controls.

III. *Objectives of the Monetary Reforms*

The European reform programs had a variety of objectives. There were first those objectives which were concerned with the prevention or the termination of inflationary spirals. Other objectives were concerned with surveys of asset distribution, the redistribution of asset holdings, and the achievement of other social goals.

Anti-Inflationary Objectives

The principal aim of many of the monetary reforms was to dampen without delay the inflationary pressures on prices and wages which appeared in force throughout Europe during the early years of the post-war period. It was generally expected that the reduction or partial blocking of liquid assets would achieve this end by reducing aggregate demand for goods and services, increasing incentives toward work, and decreasing the hoarding of goods.

The monetary reform was expected to reduce private spending in two ways. First, it was anticipated that the loss of liquidity by families and businesses would make them feel poorer, and hence out of a given disposable income less would be spent for consumption and investment goods. The removal of excess liquidity from the economy, accompanied by tight controls over bank loans, would, it was anticipated, render it

[18] The basic provisions of this reform may be found in *Bulletin d'Information et de Documentation,* Banque Nationale de Roumanie, July-Sept. 1947, pp. 152-55.

impossible for large-scale private deficit spending to occur. These expectations prevailed even in those cases in which the supply of money was not reduced at the outset, but only partially blocked for varying periods of time. Second, the very act of complying with the provisions of the monetary reforms—*e.g.*, standing in long lines before banks to surrender (permanently or temporarily) the major portion of one's liquid funds—would dampen individuals' expectations of rising prices, and it would induce them to spend less out of disposable incomes. Thus the technical provisions of the monetary reform would reduce (or partially block) the money supply, and the "psychological shock" of the program as a whole, it was thought, would decrease income velocity. In a few countries, special emphasis was placed on the shock effect as the principal virtue to be expected from the monetary reform.

The reform, by suddenly reducing the supply of liquid assets available to individuals, was also expected to increase incentives toward work. The excessive supply of these assets—relative to money national income—that was generated during the war and occupation by government deficits and export surpluses led many workers to take extended vacations after liberation. In a few countries, such as West Germany, the volume of liquid assets owned by a sizeable portion of the population was probably equivalent to one or two years' supply of consumer goods which individuals could reasonably expect to purchase under existing rationing measures. Consequently, many workers in these countries left their jobs, or worked part-time only, since an extra unit of currency from work had a zero or negative net marginal utility, whereas an extra free hour during the day to loaf or scout around for "deals" had substantially more. The monetary reform was expected to send the majority of the vacationers and "non-producers" scurrying back into the labor force as soon as they found themselves without funds.

Finally, it was anticipated that the loss of liquidity by merchants would induce them to relinquish their hoardings of inventories, and that this in turn would halt the price increases and at the same time convince the population that the reform had brought about an increase in the supply of consumer goods. Expectations of falling prices would then become prevalent and would serve, it was hoped, to dampen current spendings. The reforms were supposed to dry up black market activities and make it profitable for merchants to offer, and possible for individuals to purchase, the bulk of consumer goods in legitimate trade channels.

Other Objectives

Not all of the reforms, however, were introduced primarily for anti-inflationary purposes; in several instances, these considerations did not

even constitute immediate secondary objectives. The authorities in some countries initiated the reform programs in order (1) to conduct a survey of liquid asset distribution, (2) to redistribute liquid holdings, or (3) to achieve other social goals.

The distributional surveys were expected to serve several purposes. First, they were to prepare the way for subsequent capital levies and capital increment taxes. Capital levies were very popular in postwar Europe, and whatever success some of them had was in no small part due to the data collected during these asset inventories. The pertinent provisions called for the declaration of banknote, deposit, and security holdings, and at times other assets, as we have seen, such as insurance policies and jewelry had to be revealed. The levies were generally not designed as anti-inflationary but rather as burden-sharing measures, and in this sense the monetary reform was an indirect means of redistributing asset holdings.[19]

An aim common to all of the earlier reforms was to prevent the infiltration of old banknotes and other assets that had been carried outside the country during the occupation. This was taken care of in part by the currency provisions which declared all outstanding banknotes no longer legal tender, and which offered the opportunity to each person to exchange his old notes for new ones. By this technique the authorities were able to take stock of the banknotes still within their borders and to make certain that they (the authorities) would not be subject to future competition from potential "monetary authorities" outside the country who held large amounts of the old notes.

Another purpose of the surveys, widely advertised by many of the governments, was to catch black-marketeers and other illegal operators. As old banknotes were turned in for new ones, the authorities made special note of those individuals converting large amounts of high denomination bills—the types generally used for nefarious purposes. In many cases, deblockings were not granted until the sources of funds had been thoroughly investigated by the authorities. Lastly, the survey data were often compared with prewar data on asset holdings in order to locate the large income recipients of the occupation period, the purpose being the collection of long-overdue income taxes.

[19] It was generally recognized that the monetary reform hit only a narrow range of assets, permitting all other assets to escape. But it was sometimes assumed that those who had profited the most during the occupation had had insufficient opportunities to dispose of their liquid holdings. Also, some governments desired to remove a portion of liquid funds from circulation only temporarily. Since these funds were due to be returned to their owners, it was felt that it would be a waste of time to compute the contribution of each person on any other basis. Most of the authorities, however, planned to "equalize the burdens" by means of capital levies at a later date. Almost all countries went through the motions of applying these levies, but in many cases they were weak measures and only in small part corrected the original "inequities."

The second general objective of the reforms, more prevalent in eastern than in western Europe, was to redistribute liquid asset holdings; when the reforms were accompanied by wholesale alterations of the price and wage structures, they were often expected to redistribute incomes, too. The large volume of liquid assets, unquestionably distributed in a more uneven fashion than postwar incomes in many areas of Europe, threatened to swing a heavy share of current output toward the large asset-holding groups if they chose to reduce their holdings. Many governments, especially in eastern Europe, sought to stave this off through the reform provisions. For example, large asset holders were often accorded relatively unfavorable terms upon which their old assets could be exchanged for new ones. Prices and wage-rates were then reset to make it difficult for these same groups to accumulate large asset holdings in the future.

Finally, in some eastern European reforms, other social goals were envisaged by the authorities. These included the suppression of "capitalist elements," the achievement of farm collectivization programs, and the general strengthening of the government's position for the pursuit of future social programs. The attempt to attain these goals was reflected, in part, in the unfavorable conversion rights granted to private enterprisers and independent farmers. Also, in several cases, the reforms were introduced at the end of pay periods, which guaranteed that the workers would be caught with few cash balances, and thus would suffer relatively little from the exchange provisions.

As stated above, the majority of the reforms were intended to combat inflation. All of them, however, were concerned with other objectives as well, while a few in western Europe were initiated almost exclusively for other than deflationary purposes.

IV. *Evaluation of the Monetary Reforms*

Achievement of Objectives

How successful were the monetary reforms in achieving these objectives? Aside from their anti-inflationary aims, they appear to have been successful in the majority of cases. The banknote exchange provisions *did* alleviate several of the currency disturbances arising out of the occupation, and they enabled the authorities to counter, to some extent, black-market activities. The blocking measures presented a breathing spell to governments during which time distributional data were collected. These data were then used to make capital levies more effective. When progressive conversion rates were employed, assets were redistributed in a matter of days. When these and other forms of discriminatory rates were used, certain economic classes were probably rendered

impotent, or at least they became more amenable to their government's desires.

The reforms in France (I and II), Denmark, and to a large extent in Norway were primarily designed to achieve several of these objectives, for after the banknote exchanges and the asset inventories had been made, all or most of the blocked funds were promptly returned to their owners. In fact, France (I) did not even bother to block deposits at all, while the Danish law stated that part of the blocked funds would be released a month after the initial blocking, and the remainder three months later. Within three or four months after the introduction of the Norwegian program, the major portion of blocked accounts was released. Since, by and large, these programs accomplished what they set out to do, they must be judged successful. However, considering only the above objectives, most of the other reforms succeeded, too. For example, it appears beyond doubt that several of the eastern European countries were successful in significantly redistributing liquid assets and in furthering other socialist programs via the monetary reforms, even though these reforms were principally conceived as anti-inflationary weapons.

But the majority of the monetary reforms should be judged primarily with respect to their anti-inflationary aims, and from this standpoint the reforms on the whole were disappointing. In fact, several of them were outright failures. It is, of course, extremely difficult, if not impossible in many cases, to separate the effects of the reforms from those of other events and policies occurring simultaneously or shortly afterwards. In Belgium, for instance, only fair success seems to have been attained, but shortly after its monetary program, the Belgian government was compelled to run substantial deficits in order to meet certain expenses connected with the presence of Allied armies within her borders. These deficits almost swamped the initial, favorable effects of the reform, and render it virtually impossible to judge what the full impact of the reform might have been. The same may be stated for the Austrian (II) case, while in several of the eastern European countries the presence of tight controls over prices and wages, the radical changes in political power, the growing proportion of socialized ownership of the means of production, not to mention the lack of available data and the recent dates of three of these reforms, make it especially difficult to appraise the programs.

In a few cases, though, the verdict appears to be clear-cut. In western Europe, the reform that achieved the most impressive results was that of West Germany, and of these results the most dramatic were the return to the work force of many workers from "unproductive" occupations and idleness, and the reduction of absenteeism in the factories.

As a consequence, real output increased sharply in this country during the half-year following the sudden reduction of liquid assets. In addition, a day or two after the monetary reform the supply of goods in legal channels increased as if by magic. Although this phenomenon was due almost entirely to the diversion of goods from "black" to legitimate channels and to the dishoarding of goods by merchants who had anticipated the currency measures, the fact remains that the shop displays were sufficiently impressive to convince many that the worst was over—that consumer goods would henceforth be easily available at "reasonable" prices. Current spending patterns responded accordingly. To a lesser extent, the same phenomena appear to have taken place in Austria (III), the Netherlands, and a few other countries. In eastern Europe, most facts indicate that the USSR and Hungary (II) had a large measure of success with their reforms. Not enough time has elapsed to warrant any statement about the second reforms in Poland, Rumania, and Bulgaria.

On the other hand, Finland, Greece, and Austria (II) apparently had little or no success in dampening inflationary pressures with monetary reforms. The same may be said for the Polish (I), Rumanian (I), and Bulgarian (I) reforms, and there is no doubt that the first Hungarian program failed miserably to halt inflation. Also, inflationary pressures were not quelled to any significant extent by either the French (II) or Czechoslovakian measures.

Thus, here and there, some dramatic, anti-inflationary results were attained by countries utilizing the reforms, but there were several failures and, it appears, many partial successes only. The persistence of inflation throughout most of Europe during 1946-47, and the necessity of several countries to resort to the monetary reform a second or third time, is evidence that all of these programs did not enjoy complete success. One is forced to conclude that, on the whole, the programs achieved much less than had been expected of them.

Some Causes of Failure

What were the reasons for the complete or partial failure of some of these programs? First, the reforms were not capable of overcoming many of the supply (of goods) difficulties of the early postwar period. Second, in practice they probably did not reduce private spending to any appreciable extent. Third, they were accompanied by inappropriate government policies and other unfavorable events.

In the face of large private demands, real output in many areas of Europe during the early postwar years remained far below prewar levels. This was not due to a large volume of involuntary unemployment, but rather to such factors as the wartime destruction and neglect

of capital equipment, the neglect of land fertility, the loss of land area to the USSR, the depletion of inventories, the incapability of many to work at normal speeds for an average workday because of mental exhaustion and undernourishment, and finally to voluntary idleness. In so far as the last phenomenon was caused by excessive liquid holdings, the monetary reforms were capable of affecting work incentives, and hence dampening inflationary pressures. In some countries this was a significant factor and it was here that the reforms achieved some of their most impressive results. But, in other countries, this was not an important element in the inflationary picture, and in all cases the reforms were not designed to cope with the other supply difficulties. However, compared with other anti-inflationary weapons, the monetary reform from this standpoint was not unique; other measures would probably have fared no better and, as we shall observe below, might well have proved less effective in increasing work incentives.

The reforms were also weak anti-inflationary measures because they failed in many instances to reduce appreciably private spending. It is probable that the most serious shortcoming of these monetary programs was that they relied almost exclusively on the liquidity effect to dampen spending, and left untouched real disposable incomes; the latter were not directly affected since prices, wage rates, and other regular payments were either converted at par, or were lowered proportionately.[20] In many instances, it is possible that the liquidity effect would have been weak even if the programs had been carried out in the most effective manner. There is, of course, no way to prove this, but it can be said that, whatever the maximum liquidity effect might have been, in practice this force was probably quite weak in a number of countries for several reasons.

First, even when liquid assets were reduced at the outset of the programs, it was not impossible for families who, in the absence of the reform, would have spent less than their incomes to maintain their same rates of spending if they so desired. Some of the reforms in fact encouraged them to maintain these rates, since funds were blocked only temporarily with the tacit understanding that most or all of them would be returned eventually. It is inconceivable that temporary blocking of this sort could have had much influence on the spending habits of many families.

Second, in many cases, a large number of families probably lost little through the currency exchange provisions. To begin with, liquid assets were undoubtedly so heavily concentrated in the upper-income classes that many families in some of these countries had nothing much to

[20] In a few cases, it appears as though substantial redistributions of disposable incomes took place, which undoubtedly altered spending patterns, too.

lose during the exchange process. Since their current (real) incomes remained approximately constant, these families might well have maintained their prereform spending rates. It should also be recalled that several reforms utilized progressive conversion rates, so that even if low- and middle-income groups held sizeable blocks of liquid assets, they were often hit lightly. Furthermore, some reforms did not affect a large proportion of total liquid holdings in any case. For example, the Finnish program hit only 8 per cent of total currency and deposits. In France (II), only 5,000 franc notes were affected, while in Hungary (I) all deposits escaped the exchange provisions. Moreover, in almost every case, government and private security holdings, life insurance policies, and other forms of liquid wealth were not subject to the conversion laws. Such partial reductions probably had little effect on either consumer or business spending.

In some of the blocking programs, not only was the public under the impression that its funds (or most of them) would be released in time, but large portions of these blocked accounts actually were released so rapidly as to negate whatever favorable effects the reforms might have initially enjoyed. Funds were not only readily deblocked for the payment of taxes, the purchase of government securities, and for emergency expenditures (the latter were sometimes defined as those expenditures which the family was in the habit of making but which it could not make now that its funds were blocked!), but blanket releases were made in such volume as to quickly undermine the reform measures. This was true in varying degrees in Belgium, Czechoslovakia, Austria (II), and the Netherlands.

Finally, in practice, the liquidity effect may also have been weak due to the fact that some of the reforms might have given rise to anticipations of second or third programs. To the extent that this was true, individuals and businesses would be reluctant to hold currency and deposits for fear that these assets would be hit again. To protect oneself against the type of monetary reform conducted in Europe, one had only to consume income or to hold wealth predominantly in either real assets or, in most cases, private securities. There is some evidence that the Austrians and Hungarians reacted unfavorably to their initial reforms, and it would be surprising if families in Rumania, Poland, and Bulgaria were not at this time hesitant to hold the types of assets affected by the two reforms in each of those countries. One monetary reform may not give rise to a flight from money, but it is extremely doubtful that most individuals will remain calm after a second or third program within, say, a five-year period. It is probably true that monetary reforms are also subject to diminishing returns.

Through no fault of their own, several of these measures failed to

halt inflation because of inappropriate government actions which accompanied or shortly followed them. These included relatively high government expenditures coupled with inadequate tax receipts, and easy bank credit policies.

Government expenditures in many European countries during 1945-46 were "necessarily" large for a number of reasons. First, several countries were compelled to meet partially the expenses of the Allied armies situated within their borders. Others were required to pay reparations, and all felt obligated to meet partially the costs of reconstruction of homes and factories, the rehabilitation and relocation of large segments of the population, and other social welfare programs. Primarily in eastern Europe after 1947, but also in some western European countries (such as Norway), heavy industrialization programs necessitated large government outlays. These spendings, coupled with large private spendings out of relatively high disposable incomes, soon offset, in some countries, the initial, favorable effects of the reforms.

But, would it not have been possible to boost tax rates to levels sufficiently high to offset the inflationary impact of these governmental outlays? There are simply too many countries under consideration here to permit a general answer to this question. However, a few factors, common to most countries, suggest that an all-out *income* tax program in 1945-46 to accompany the monetary reforms might not have been feasible or possible. Many governments were not able to move rapidly in the income tax field for lack of trained personnel to handle the job. In some instances, it would have required years to gather together and train these personnel.[21] But, even if the administrative set-up had been adequate, it was considered quite likely that higher income tax rates might yield only a small increase in tax revenues. Tax morality was at its lowest ebb immediately after liberation, in large part because the evasion of regulations during the occupation was considered by many as honorable, and these attitudes were carried over into the postwar period. When this factor was linked, in the minds of the authorities, with the longstanding propensity of farmers and other groups, in some areas of Europe, to evade taxes, income taxation as a main weapon

[21] Nor was it possible for many of these governments to impose widely based capital levies immediately after the war. The pertinent information of wealth distribution was not on hand, and it would have required months, perhaps years in some cases, to bring together these data. On the other hand, the monetary reform dealt only with those assets whose ownership patterns were known, or could be known in a short period of time. Bank deposits were ideal assets from this standpoint, while banknotes, unlike bathtubs and land, could be recalled and exchanged for new ones on the terms set by the authorities. The major share of the administrative tasks fell on existing financial institutions which had only to increase their staffs to handle the extra loads. These tasks were lightened, of course, by the very nature of the assets affected, which made evasion of the provisions of the law practically impossible.

against inflation did not seem to offer much promise of success. In any case, however, the fact remains that an inadequate tax program, given the relatively high levels of government expenditures, upset the reform's applecart in several of these countries.

The initial effects of a few of the reforms were also negated by credit policies which were incapable of preventing sharp increases in bank loans to businesses and individuals subsequent to the monetary reforms. If funds could not be deblocked, large private spendings were occasionally financed by supplementing current incomes with bank borrowings; sometimes, the collateral used was the blocked deposit! Such was apparently the case in Austria (II), Greece, and one or two other countries. Many governments for social reasons were reluctant to raise interest rates. Higher rates would have had a disturbing influence on house building and on rents of new houses,[22] and would have yielded higher incomes to the rentier class. Debt management considerations, as in this country, sometimes were successful in preventing upward movements in the interest rate structure.

V. Conclusion: Monetary Reforms and Orthodox Measures

The excessive volume of liquid assets in Europe apparently exerted its effects in at least two ways: (1) It increased private spendings out of disposable incomes, and (2) it weakened work incentives. In many of these countries the first phenomenon appears to have largely overshadowed the second. In others, the second phenomenon was particularly potent. Such nonuniformity in the liquidity effect was, to a large extent, due to differences in the volume of excess liquidity existing in these countries. As individuals gained excess liquidity, it is quite likely that their attention was first directed to the possibility of increasing their spending and not to the possibility of reducing their working hours. However, as excess liquidity continued to grow, attention was turned more and more to the second possibility. Some individuals worked fewer hours per day, or fewer days per week, but for many there was little leeway to adjust these hours. The relevant decision, in many cases, was whether to continue work or to quit work altogether, and such a decision was a major one. Therefore, only when excess liquidity had reached very large proportions did a significant segment of the labor force voluntarily give up work for a time to live off accumulated assets. On the other hand, spending probably grew continuously as liquidity grew, even though the total liquidity effect on spending might have been weak.

Thus, the results of the monetary reforms were almost bound to be

[22] See, B. Ohlin, *The Problem of Employment Stabilization* (New York, 1949), p. 23.

more dramatic in some countries than in others, aside from differences in the administrative efficiency and vigor with which the reforms were carried out. For many countries, the most that could be hoped for was some slackening in the rate of spending once excess liquidity had been removed. In those cases in which the liquidity effect on spending proved to be slight, the monetary reform was not a potent anti-inflationary weapon. Moreover, even where this effect might have been potentially large, in practice, as we have seen, various defects in the reforms themselves weakened their impact on spending. On the other hand, in those few countries where excess liquidity had grown so large as to affect seriously work incentives as well as spending, the reforms appear to have been highly successful in spite of several of the same types of defects which were found in less successful reforms. While these defects frequently weakened the liquidity effect on spending, they probably seldom weakened this effect on work incentives. For example, temporary blocking might not have altered significantly the spending habits of individuals who were currently working, but it undoubtedly induced the majority of the voluntarily idle to return to work. Thus, where the monetary reform was least needed it had to be highly efficient to be at all effective, and where it was most needed it could suffer certain defects and still succeed admirably.

Would it have been possible for many of these countries, from the standpoint of inflation control, to have dispensed with the monetary reform altogether? That is, aside from administrative and similar considerations, would it not have been possible for these countries to have dampened inflationary forces with higher income taxes and tighter credit controls, without the utilization of the monetary reform at all? While no general answer to this question is possible, one suspects that in several countries the reforms would have been of no great value as anti-inflationary measures, even if they had been carried out with the highest efficiency. For example, in Finland the inflation was largely due to a heavy rate of investment spending which set off a price-wage spiral. Investment spending was heavy because of refugee reallocation problems, the reconstruction of Northern Finland, and the necessity of building new industries to meet reparation demands from the USSR. In the face of this situation, the 1945 monetary reform, which reduced the volume of banknotes in circulation, was a straw in the wind. The introduction of monetary reforms in such cases was due either to factors that had little direct connection with inflation control—such as taking inventory of banknotes still within the country—or to a misplaced emphasis on quantity theorizing which led many authorities to focus their attention on "stocks" to the neglect of flow magnitudes.

But in many countries the reform, or something similar to it, was probably an essential part of any over-all program to control inflation. This was obviously true in such countries as West and East Germany and Austria where excess liquidity had largely destroyed work incentives. But the case for the monetary reform was almost as compelling in the other countries. Consider the alternative measures faced by the authorities in these countries. So far as income taxation was concerned, the impact of excess liquidity on spending meant that, with a given rate of government expenditures, tax receipts had to comprise a larger proportion of national income than they otherwise would if inflation were to be avoided. But since excess liquidity also made individuals less dependent on their current incomes for current expenditures, a given ratio of tax receipts to national income was more likely to kill incentives toward work than if excess liquidity had not been present. Thus, the existence of this liquidity created a dilemma for the authorities in a number of European countries. An excessive volume of liquid assets necessitated an increase in tax rates and at the same time made it especially dangerous, from the standpoint of incentives, to maintain the existing level of rates.

Central bank measures were also probably weak in a number of countries in which liquid holdings were excessive. The presence of these holdings undoubtedly made some families and business firms less dependent on bank loans as supplements to their current incomes, and hence less sensitive to changes in interest rates and in the tightness of the money markets. Furthermore, orthodox monetary policy was not capable of significantly altering the total supply of liquid assets, even though it was capable of altering the composition of that supply. In some countries, excessive liquidity created too many "self-sufficient islands" within the economy for the successful pursuit of conventional monetary measures.

The authorities in some countries also felt that, in the presence of a large stock of liquid assets, the continuance of direct controls over prices and wages—that is, the continuance of the disequilibrium system—would be futile. In many areas of Europe, the termination of fighting brought with it not only a decreased desire to obey regulations but also widespread anticipations of rising prices as part of a postwar inflation. In addition, large segments of the population had little desire to go on accumulating claims to output in the face of an already abundant supply of these claims. Even if work incentives had not been seriously impaired at the time, there was always the danger that the continuance of the disequilibrium system would ultimately lead to a general deterioration of these incentives. The West German case is, of

THE INTERNATIONAL TRADE PHILOSOPHY OF CORDELL HULL, 1907-1933

By WILLIAM R. ALLEN*

"We urgently need more economics and less selfishness and politics in dealing with tariffs." Cordell Hull, *Congressional Record,* April 14, 1926, p. 7472.

It is a commonplace that economists generally, and perhaps international trade theorists more than most, have not been permitted to make their maximum potential contribution to the formulation of public policy. Typically, men slightly versed in economic principles and little inclined to consult the academic specialist have framed our commercial policies. In light of the divarication in this field between the policy-maker and the economist, it is rather curious and certainly unfortunate that very limited study has been devoted to tariff debates.[1] Economic analysis usually has been conspicuous by its absence or perversion in the determination of American tariff policy; and economists have been disinclined to concern themselves with the problems either of how best to disseminate their reasoning and conclusions among legislators and the community or of the consequences of the imperfect mobility of their ideas.[2] In any case, whether the economist should strive generally for a more active rôle in formulating policy or be content with a passive, spectatorial mission of detached analysis, it behooves him not to abandon entirely the study of legislative deliberations and processes to the political scientist, the historian, and the psychologist.

* The author, who is assistant professor of economics at the University of California, Los Angeles, wishes to acknowledge the comments and suggestions of Professor R. S. Smith. The work was largely completed while the author held a fellowship of the Social Science Research Council.

[1] One exception is the survey of the 1929-30 debates by F. W. Fetter, "Congressional Tariff Theory," *Am. Econ. Rev.* (Sept. 1933) XXIII, 413-27. An analysis of the congressional committee hearings on the Hawley-Smoot bill is given by E. E. Schattschneider, *Politics, Pressures and the Tariff* (New York, 1935).

[2] Naturally, this is not to suggest that the point of view and the pressures affecting the mode of analysis are, or should be, identical for both the policy-maker and the academic economist. See Jacob Viner, "The Short View and the Long in Economic Policy," *Am. Econ. Rev.* (March 1940) XXX, 1 ff. Fetter (*op. cit.*, p. 427) appears too sanguine in discounting the low quality of congressional debates as being merely a reflection of the public's ignorance and nationalistic inclinations. This is not the place to discuss the implications in political theory of this interpretation. But for purposes of economic analysis, we should do well to heed Viner's admonition against concluding that, because the theories of a period can be *explained* in light of the circumstances then prevailing, the theories (and congressional debates) can also be *justified* by appeal to these special circumstances. Jacob Viner, *Studies in the Theory of International Trade* (New York, 1937), pp. 110-11.

This article is concerned with the views on foreign trade of Cordell Hull during his years in Congress.[3] Hull's unusual interest and competence in the field of international economics made it possible for him to be "both the spearhead of the movement towards a more liberal policy for the United States and a substantial part of its driving force."[4] Thus, the history of the Trade Agreements Program, which has furnished the core of United States economic foreign policy since 1934, would be inadequately told without consideration of the long-held views of the statesman from Tennessee.

A review of the early international trade views of Hull may be considered a case study of congressional trade theory. As such, the speeches and statements of Hull are both good and bad: good because they were given over a period of more than a quarter of a century and were the product of a consistent, intelligent and conscientious public servant; bad because, by his virtues, he was rather an atypical congressman. Hull's theorizing, for all of its lack of sophistication as measured by the standards of the professional economist, was considerably higher in quality than that of almost all his colleagues.

To Hull the commercial aspects of foreign policy were always of paramount importance. He traces his interest in the tariff and other problems of trade to his first excursion into politics when, at the age of sixteen, he participated in the Cleveland-Harrison campaign of 1888.[5] In his first year in Congress, he decided to specialize in "revenue, tariff, and other forms of taxation, economics, and finance."[6] The basic elements of his thought were held consistently throughout his career, and it needs only to be mentioned that his approach to trade policy enlarged during the first World War from considering the subject as just a domestic issue to viewing it also as a key to the problems of international welfare and peace.[7]

I. *The Gains From Trade*

Nature and Purpose of International Trade. To the economist, international trade theory centers around two points: the reason for and the

[3] Hull had a long and significant career in Congress. He held a seat in the House of Representatives from 1907-30, except for the years 1921-23, and was elected to the Senate in 1930, resigning from the upper house in 1933 to become Secretary of State. From 1921-24, he acted as chairman of the Democratic National Committee. He was Secretary of State for almost twelve years—longer than any other man has held the position.

[4] H. J. Tasca, *The Reciprocal Trade Policy of the United States* (Philadephia, 1938), p. 82. Tasca presents a brief summary of Hull's trade philosophy (pp. 82-85).

[6] *Ibid.*, p. 46.

[7] *Ibid.*, pp. 81, 84, 100-01, 352, 363-64. See also H. B. Hinton, *Cordell Hull: A Biography* (New York, 1942), pp. 148, 159, 163.

essential basis of trade (emphasized in the Heckscher-Ohlin approach); and, given these conditions of trade, the distribution of specialization and the direction of trade, and the gains from such specialization and exchange (still largely associated with the orthodox Ricardo-Mill-Marshall-Taussig line of thought). Except for the question of the gains from trade, Hull largely ignored these topics, and the gains which he discussed generally were not those stressed in economic theory.

He did not attempt a formal statement of the comparative cost principle. While he paid considerable attention to the interdependence of imports and exports, he did so in connection with specific problems of trade policy and in reference to the *mechanism* of trade, not in regard to its basic nature and purpose. "Foreign trade," he said, "is really the mutually profitable exchange by nations of their surpluses."[8]

> International trade is simply a system of barter or exchange of goods and products between nations. Each nation must sell its surpluses to other nations needing or desiring them, while in turn it purchases from others such goods and commodities as it may specially desire, chiefly those it does not itself produce at all, or in sufficient quantities, or the production of which is not economically justifiable.[9]

Generally, Hull was much more impressed with the advantages of disposing of surpluses than with those of obtaining imports. The chief gain which did accrue from imports was lower production costs because of cheaper raw materials. Lower costs not only would allow cheaper prices for the benefit of the consumer but also would enable the producer to compete in the markets of the world, which, in turn, would both raise the general level of economic activity and contribute to the community's welfare.[10] But he emphasized that international trade "does not mean the displacement of established home production and trade of one country by that of another." On the one hand, imports are largely noncompetitive, being either raw materials not domestically

[8] *Congressional Record*, Apr. 14, 1926, p. 7472.

[9] *Ibid.*, May 10, 1926, p. 9103; see also *ibid.*, Dec. 22, 1920, p. 634; Department of State *Press Releases*, June 17, 1933, pp. 448-49. (On this point, as on many others in the remainder of the paper, the author is prepared to furnish extensive documentation. Limitations of space make necessary only sample citations.) These statements are rather intriguing in their similarity to classical dicta. See Viner, *Studies*, ch. 8, 9. Note particularly J. S. Mill's criticism (*Principles of Political Economy*, W. J. Ashley, ed., pp. 578-80) of Adam Smith's declaration (*Wealth of Nations*, Modern Library ed., p. 415) that one of the major advantages of trade is that "it carries out that surplus part of the produce of their land and labor for which there is no demand among them, and brings back in return for it something else for which there is a demand."

[10] *Cong. Rec.*, June 9, 1911, p. 1816; *ibid.*, Dec. 19, 1925, pp. 1182, 1184; *New York Times*, June 24, 1929, 10:2. In 1923, he repeatedly urged a reduction in the sugar tariff for the benefit of consumers. *Ibid.*, March 24, 1923, 1:3.

available or semimanufactured and finished articles which cannot be profitably produced at home in sufficient quantities. On the other hand, disposal of exports generally involves the locating and developing of new customers and new markets for surplus production.[11]

Employment Effects: The Disposal of Surpluses. The point which Hull stressed probably more than any other after the war was the necessity of selling surpluses abroad. In 1919 he stated that "the biggest factor in our domestic prosperity during the coming years will be our foreign trade,"[12] and the export of "these ever-increasing surpluses" was the essence of the foreign trade problem.[13] The United States, so his argument ran, is the world's greatest producer. Indeed, we produce vastly more of many commodities than we can consume—the capacity to consume evidently being an absolute quantum, unaffected by possible alternative prices or income levels. Since, with reasonably full employment, we produce large surpluses, exports are essential, although the inflated export values of the war period would naturally decline somewhat. Our economy *must* enjoy substantial exports, or there would inevitably result permanent unemployment and stagnation, only partially relieved by "dumping" abroad.[14] The moral was clear, assuming that we did not wish to curb the development of our productive potential: we must vigorously promote our export trade, in which policy "super-protection" could be nothing but an anomaly.[15] "Our chief expansion must be beyond the seas."[16]

With his strong conviction that there is a significant causal relation running from trade policy to the level of economic activity, it was perhaps inevitable that Hull would claim that "every important panic since the Civil War has occurred either under Republican high-tariff admin-

[11] *Cong. Rec.*, Dec. 19, 1925, p. 1182; *ibid.*, May 13, 1929, p. 1208.

[14] While an artificial curtailment of trade results in losses because of misallocation of resources, it does not necessarily involve losses through unemployment; and thus, as mentioned earlier (see note 9), Hull repeats an error of Smith and as well deserves the censure of Mill. It is not here implied that Mill's analysis, which assumed perfect mobility of resources and was in the tradition of Say's Law, is adequate. Nevertheless, it is not essential—as Hull declared—to rely upon trade policy to maintain high national income. It should be added that Hull did not speak in terms of an export *balance*, and in the 1930's he denied any motive to promote such a balance. Quite the contrary, he recognized that exports must sooner or later be matched by imports and vigorously condemned beggar-thy-neighbor policies. Thus, while his analysis implies perfect immobility of resources now in export industries, he evinced little concern over the possibility that immobile factors in nonexport industries might be embarrassed by increased imports.

[15] *Cong. Rec.*, Feb. 21, 1919, pp. 3955-56; *ibid.*, Mar. 11, 1924, p. 3948; *Press Releases*, May 6, 1933, pp. 312-13, 313-14, 315.

istrations or their high-tariff legislation."[17] The Great Depression, following a period of boom which was not the result of high tariffs, was no exception. The "half-insane policy of economic isolation during the past ten years by America and the world under American leadership is the largest single underlying cause of the present American and world panic. . . ."[18] Almost every nation, in the interests of self-sufficiency, sought at once to stimulate production and to curtail trade, with the inevitable result of unsold surpluses, a disrupted commercial system, and disjointed economies.[19] A necessary, although not a sufficient, condition for the restoration of prosperity—in addition to "indispensable and all-important" domestic programs—was the opening of the markets of the world to the natural flow of surplus commodities.[20] At the London Economic Conference, the Secretary of State emphasized that an effective policy to this end must, in some form, be multilateral:

> . . . nations are substantially interrelated and interdependent in an economic sense with the result that international cooperation is a fundamental necessity. . . . Many measures indispensable to full and satisfactory business recovery are beyond the powers of individual states. . . . It is equally true that mutually profitable markets could only be obtained by the liberalization of the commercial policies of other countries and this is only possible by the simultaneous action of all governments stabilizing exchange and currencies and reducing to a reasonable extent trade barriers and other impediments to commerce between nations.[21]

Political Stability and Peace. After becoming Secretary of State, Hull put much emphasis on the economic foundations of political relations. He did not stress this consideration during his years in Congress,[22] although several times he indicated his belief that the major causes of war are economic in nature.[23] And in 1929 he prophetically warned: "Economic questions more than all others will engross the attention of

[17] *Ibid.*, Feb. 21, 1926, p. 7472.

[18] *Ibid.*, Mar. 24, 1932, p. 6788. "Had international trade, unfettered by universal tariff barriers, been permitted to increase according to the pre-war ratio, the many millions of unemployed wage earners in this and other countries would today be employed at full time." *N.Y. Times*, Feb. 16, 1931, 20:1.

[22] Hull's own account of his intellectual development (see citation in note 7) indicates a greater concern in the political implications of foreign economic relations than is evidenced in his congressional addresses and statements.

[23] *Cong. Rec.*, Dec. 9, 1919, p. 8743; *ibid.*, Mar. 24, 1932, p. 6793.

this country and the world for many years to come."[24] It was essential, therefore, in a world of growing economic interdependence, to achieve such reforms in commercial practices as would eliminate many of the causes of political conflict.[25]

A condition of general depression tended to increase the intensity of economic fears and rivalries. The chaotic economic situation of the early 1930's was, Hull felt, largely responsible for social unrest, degeneration of "international ethics," and the threat of eventual military conflict.[26]

Opportunities for Leadership. Throughout the period from the end of the first World War to the depression, Congressman Hull urged that America, in the face of new global economic conditions, should adopt a liberal commercial policy. The war had wrought both physical and financial changes: the immediate productive power of Europe had been reduced and disorganized while that of the United States had greatly expanded—raising the problem of "surplus" production here; the United States had been transformed from a debtor to a creditor; our share of the world's gold and of world trade was greater than before the war; whereas foreign trade generally was demoralized, we had experienced a trade boom during and just after the war, with the value of foreign trade becoming a much larger percentage of domestic production than in previous years. In short, the United States had been thrust into the "dominant position in the financial and commercial affairs of the world."[27] Hull continued in the late 'twenties to insist that this country possessed extraordinary trade opportunities which should be eagerly exploited.[28]

Shortly after the elections of 1920, he observed that the United States faced the "momentous question" of whether it would adopt the "wise and philosophic policy" of maintaining "our present supreme position in world finance, commerce, and industry," through a liberal and

[24] *Ibid.*, May 13, 1929, p. 1203.

[25] "Economic peace offers the greatest assurance of permanent world peace. Artificial trade barriers invariably create bitter trade rivalry, vicious trade practices, and economic wars, which in modern times have been the prelude to actual wars. Commercial power or control means political control and often military control as well. It becomes all important, therefore, to reduce to a minimum those trade discriminations, obstructions, and monopoly combinations, which breed serious antagonisms and strife in the efforts by nations to extend their commercial interests." *Ibid.*, Dec. 19, 1925, p. 1184; see also *ibid.*, Feb. 26, 1915, pp. 4766, 4768; *N.Y. Times*, July 25, 1931, 1:7.

[27] *Cong. Rec.*, Dec. 22, 1920, pp. 631, 632, 635; *ibid.*, Mar. 11, 1924, p. 3947. Even before the war, Hull chided his high-tariff opponents for their lack of confidence in the ability of the American producer to compete in world markets. *Ibid.*, June 11, 1911, p. 1817.

[28] *Ibid.*, Apr. 14, 1926, pp. 7473, 7475.

vigorous commercial policy,[29] or whether it would "as the only alternative adopt the narrow, short-sighted, suicidal policy of commercial isolation."[30] But proper trade policy was much more than a purely domestic issue. He correctly observed in 1919 that conditions then prevailing would lead naturally to a readjustment of tariffs and of commercial relations, which would "offer a strong incentive to the renewal of tariff wars." It was thus of paramount importance to secure the general adoption of "certain prohibitions by which both individuals and nations shall be governed in their international financial and commercial activities, thereby eliminating . . . unfair, hurtful, and trouble-making practices and methods. . . ."[31] He considered the immediate postwar period a most propitious time to call an international trade conference, leading perhaps to a permanent trade-agreement congress or an arbitration tribunal, to establish "a code of commercial ethics," and he deplored the failure of the Paris Peace Conference to achieve an international agreement to abandon the more vicious trade practices.[32]

[29] One of the elements of such a policy would be "negotiating wise reciprocal commerical treaties."

[30] *Ibid.*, Dec. 22, 1920, pp. 634-35.

[31] *Ibid.*, Feb. 21, 1919, pp. 3956-57.

[32] *Ibid.*, Feb. 21, 1919, pp. 3955, 3956, 3960; *ibid.*, Dec. 9, 1919, p. 8743. In February 1916, Hull had prepared a resolution, which in modified form was introduced in the House in April 1917, calling for a trade conference at the end of the war. In 1916, Hull submitted a copy of his resolution to Secretary of State Robert Lansing and asked for the latter's view of the wisdom of offering the resolution in Congress at that time. Hull said he had "in mind the generally accepted fact that the chief underlying cause of the present European war is accounted for in the strenuous trade conquests and bitter trade rivalry being conducted prior to the outbreak of the war. . . ." Also, largely for the sake of its own commercial welfare, it was "very important and necessary" for the United States to forestall the formation of economic unions by either the Allies or the Central Powers to conduct economic warfare after the military armistice. National Archives, State Decimal File 1910-29, 600.0031/2, letter from Hull to Lansing, Feb. 16, 1916. It was the opinion of C. A. Holder, Foreign Trade Adviser in the State Department, that "unquestionably both the allied and central powers would resent bitterly any such proposal made at this time or even made after the war." During the war, it was "absolutely impossible . . . to discuss such a question." "After the war undoubtedly groups . . . will continue to wage economic war on each other unless the decision is so decisive that the loser will be unable to resist the dictation of the winner. In any event the victorious side would not welcome our interference nor if the war should become a draw would our suggestions be welcomed as economic conditions in both groups will be so radically different from ours that the measures they may have to take to regain a part of their commerce will not be at all similar to measures that we have taken or will take in the future." *Ibid.*, memorandum from Holder to F. C. Polk, Counselor, Feb. 19, 1916. Lansing replied to Hull that the opinion of the Department was that "such a proposal would undoubtedly prove unacceptable to the belligerent powers at this time. . . ." *Ibid.*, "personal and confidential" letter from Lansing to Hull, Apr. 1, 1916. In later years, Hull continued to advocate international conferences on commercial relations. *N.Y. Times*, Jan. 6, 1922, 2:4; National Archives, State Decimal File 1910-29, 550.M1/68, memorandum by Wallace McClure of conversation with Hull, Feb. 8, 1927; *Cong. Rec.*, May 19, 1932, pp. 10638-39.

But the United States persisted in its refusal to recognize that "we are in a new era, which calls for new policies." Far from assuming leadership in liberal and friendly commercial policies, we were, Hull insisted, largely responsible for the widespread growth of extreme trade barriers.[33] To the end of his career in Congress, and after, he pleaded for a change in the direction of American leadership, which, "while disclaiming economic internationalism, would challenge economic nationalism and pursue a sane, liberal, middle course. . . ."[34]

II. *The Losses From Protection*

The evils and dangers of a policy of protection were described at considerable length by Hull, frequently in a scathing and indignant manner.[35]

Inequality of Tariff. He considered it perfectly self-evident that the protective tariff was an unwise and unfair tax. Without attempting rigorously to trace the income-distribution effects of the tariff, he often charged that the duties benefited only favored and greedy manufacturers by raising prices, thus extorting from the great mass of consumers a subsidy for the wealthy few.

> . . . our system of high protective-tariff taxation is an outrage in its operation and effects. It is conceived upon the idea that the people should be taxed according to their needs and practically according to their poverty.
>
> A protective tariff, speaking generally, is immoral and dishonest, because its sole purpose is to increase prices artificially, in certain instances, thereby enabling one citizen to levy unjust tribute from another.[36]

Inefficiency and High Costs. The basic economic purpose of international trade is to make possible a more efficient allocation of resources within the respective national units of the world economy than would be feasible or possible if each unit were forced to be self-sufficient. Unfortunately (from the economist's viewpoint), Hull did not pursue this analysis, aside from criticizing tariffs on the ground that they raised

[33] *Cong. Rec.*, Dec. 22, 1920, pp. 632, 633; *N.Y. Times*, Mar. 1, 1926, 10:1; *Cong. Rec.*, Apr. 8, 1932, pp. 7746-47.

[34] *Ibid.*, Dec. 19, 1925, p. 1182; *ibid.*, Jan. 3, 1929, p. 1072; Department of State Files, 550.S1 Wash./48, Apr. 8, 1933.

[35] He castigated the Payne-Aldrich Act of 1909 as "that abominable iniquity, that ghastly abortion." *Cong. Rec.*, Sept. 25, 1914, p. 15721. Other descriptions of the protective system included: "the sleepless monster of protection . . . vicious class legislation" (*ibid.*, June 9, 1911, p. 1812); "the personification of avarice and selfishness," "this system of diabolical extortion" (*ibid.*, Mar. 16, 1912, pp. 3498, 3501).

[36] Respectively, *ibid.*, Mar. 16, 1912, p. 3498; *ibid.*, Feb. 26, 1923, p. 4670. See also *ibid.*, Mar. 18, 1908, p. 3519; *ibid.*, May 13, 1929, pp. 1203, 1209.

production costs, the major consequence of which was the handicapping of our efficient export trade.[37]

He further complained that American tariffs had been framed "not only to protect the weakest and most inefficient industry . . . , but the most inefficient individual business in that industry. They are framed to protect overcapitalization, water capital, inefficient management, obsolete and antiquated machinery and plants, and also to protect against freight rates across our 3000-mile continent."[38] Moreover, under the protection of barriers which prevented "reasonable competition," many manufacturers had been "lulled into inefficiency."[39] There was thus a reciprocal relationship: inefficient industries obtained tariffs, and tariffs begat inefficiency.

Fostering of Monopoly. In the Roosevelt-Taft "trust-busting" period, Hull charged that the protective tariff, a product of Republican administrations, had been responsible for monopolies and trusts "springing up like mushrooms." Favored interests were allowed "free rein to their unbridled appetite for gain and their wicked lust for power."[40] In late 1920, he made the pertinent observation that those congressmen who were most insistent on relaxing governmental restrictions on business were the ones who also were rabidly advocating the "artificial economic barrier" of a protective tariff.[41] For Hull, the ideal of a competitive economic order embraced the ideal of a "competitive" tariff.

Labor and the Tariff. Hull effectively attacked the popular pauper-labor argument "that American manufacturers must have these extortionate tariffs in order to protect reasonable wage scales."[42] First, he maintained that, historically, the high postwar tariffs had not been the cause either of the welfare of labor specifically or of prosperity generally. High wages, high living standards, and shorter working hours "had become a permanent part of our industrial system prior to the Fordney tariff" of 1922—and they originally appeared in non-tariff-sheltered industries. The "partially satisfactory business conditions" of the 'twenties resulted, not from the tariff, but from our great resources, mass production and increased productivity, varied capital expansion, the credit structure, and installment sales.[43]

[37] See p. 103, above.

[38] *Ibid.*, May 13, 1929, p. 1205; see also *ibid.*, Dec. 19, 1925, p. 1183; *N.Y. Times*, Feb. 16, 1931, 20:1.

[39] *Cong. Rec.*, Dec. 19, 1925, p. 1183.

[40] *Ibid.*, Mar. 18, 1908, p. 3519; *ibid.*, Mar. 29, 1909, p. 532; *ibid.*, Aug. 13, 1912, p. 10835. See also *ibid.*, May 13, 1929, p. 1208.

[41] *Ibid.*, Dec. 22, 1920, pp. 632-33.

[42] *Ibid.*, Dec. 19, 1925, p. 1183.

[43] *Ibid.*, Jan. 3, 1929, p. 1072.

Second, only a small proportion of the wage earners "are in a position to receive any increased wage benefits from tariffs, even theoretically."[44] Third, for the most part, wages were lower and working conditions poorer in the highly protected industries than in the unsheltered segments of the economy.[45] Similarly, although the United States had enjoyed high wages under protection, many high tariff countries had much lower living standards than had free-trade England.[46] Finally, Hull indicated a respectable comprehension of "efficiency wages."

> The increase of productivity, or the output per man, is the outstanding factor in our high wages and high living standards. . . . There is always a close relation between the productivity of labor and the wages paid. A low wage naturally goes with low industrial efficiency, and generally means a high labor cost.[47]

Although he did not state with precision the relation of the limit of international wage-rate ratios to productivity ratios, he called attention to the fact, in 1920, that the United States was exporting goods and services valued at eight billion dollars "in utter defiance of the competition" of pauper labor.[48]

Agriculture and the Tariff. Protectionists claimed that farmers, like laborers, were major beneficiaries of the tariff, while in fact, Hull insisted, the only ones who had become wealthy as a result of protection were a few manufacturers. Agriculture had been deluded by industry into supporting a high-tariff policy, and unless it soon understood that its best interests lay in the opposite direction, it was destined to a state of permanent decay.[49] The agricultural depression of the 'twenties could be "immediately and effectively" relieved by reducing tariffs and freeing international trade.[50]

American agriculture was so efficient, Hull's analysis ran, that it not only produced more of many commodities than could be sold in the home market, but it exported a great deal—and needed to export much more. Where exports were a large proportion of total production, agri-

[44] *Ibid.*, May 13, 1929, p. 1206. Hull gave several estimates of this proportion, but he indicated that of the 40-45 million gainfully employed in the late 'twenties, about 6 million were in "tariff-sheltered industries." *Ibid.*, Apr. 14, 1926, p. 7475; *ibid.*, May 13, 1929, pp. 1206-07. But in 1932, he apparently thought that only 15-20 percent of the 8½ million wage earners in manufacturing could hope for tariff benefits. *Ibid.*, Apr. 8, 1932, p. 7746.

[45] *Ibid.*, Mar. 11, 1924, p. 3948; *ibid.*, Feb. 15, 1927, p. 3898.

[49] *Ibid.*, Apr. 14, 1926, pp. 7472, 7478; *ibid.*, May 10, 1926, pp. 9099-01, 9102, 9103; *ibid.*, May 24, 1932, p. 10998.

[50] *N.Y. Times*, Sept. 24, 1923, 4:2.

cultural or otherwise, the world price tended to prevail also in the domestic market. Generally, the American farmer already had the home market, and keeping out driblets of competitive imports could have no appreciable effect on either the prices or the income received by agriculture. The only possible results to the farmer of a high tariff policy would be an artificial raising of the prices of things he bought—thus creating a price disparity, with the farmer selling in a "free" market and buying in a protected one—and a curtailment of exports generally, including farm products.[51]

III. *The Interdependence of Imports and Exports*

Must Import to Export. While, to Hull, the chief advantage of international trade was the disposal of surpluses, he realized generally that foreign sales are limited by imports of some sort. Gold flows and loans were factors in determining the level of balance in the international payments, but he appreciated the fact that one-way movements of gold and loans could not be expected to continue indefinitely.[52] Basically, "for every dollar of merchandise exported there must sooner or later be a dollar of the same imported."[53]

United States Loaning Policy. Hull naturally felt a certain ambivalence toward the great flow of American loans abroad which continued throughout the 'twenties. For while the billions of dollar exchange thus advanced to foreigners made possible the all-important disposal of our surpluses, it seemed to him apparent that "merely piling new upon old debts" was not an acceptable foundation for a long-run commercial policy.[54] Precisely what his objections were to "excessive" foreign loans, he did not make clear, although his language suggested that this stimulus to export trade was "artificial," inadequate, and unsafe. Also, "the more we loan the more must be paid back with interest by some means."[55]

Receiving Payment of Foreign Debts. Hull ridiculed the attitude that the United States should both insist on foreign nations repaying loans and at the same time restrict imports, but he criticized those who

[51] *Cong. Rec.*, Dec. 22, 1920, pp. 633, 636-37; *ibid.*, Feb. 26, 1923, pp. 4671, 4668-70; *ibid.*, May 10, 1926, pp. 9098-99, 9101, 9102-04.

[52] "Save for these factors [foreign loans and receiving gold] our foreign commerce would present a deplorable situation today. We cannot continue indefinitely to pile up great menacing surpluses of idle gold, any more than we can continue to finance a large portion of our exports by huge foreign loans." *N.Y. Times*, Nov. 18, 1925, 25:1.

[53] *Cong. Rec.*, May 13, 1929, pp. 1208-09; see also *ibid.*, Dec. 22, 1920, pp. 632, 634; *Press Releases*, May 6, 1933, p. 314.

[54] *N.Y. Times*, Nov. 18, 1925, 25:1; *Cong. Rec.*, Jan. 3, 1929, p. 1073.

[55] *Ibid.*, Apr. 14, 1926, p. 7473.

proposed that we cancel, in whole or in part, foreign indebtedness only for the purpose of obviating the necessity of increasing our imports.[56] He understood that receiving debt payments would, indeed, necessitate large imports (although he did not speak of an import balance), and that our high tariff policy had seriously hampered the repayment process, but the appropriate policy was to liberalize trade and accept the imports, not to ignore the foreign obligations.[57] Even in the midst of the depression, Hull held that there was no compelling reason to write off any of the foreign debts, although leniency should be shown to the debtors. "Of what avail would it be to sidetrack the war debts upon the theory of increasing international trade, while leaving intact the insurmountable tariff and other trade and finance obstructions that bristle on every national frontier and render trade virtually as impossible without war debts as with them?"[58]

IV. *Tariff Criteria and Purposes*

Equalization of Production Costs. Hull recalled that in earlier years, particularly until the middle of the nineteenth century, advocates of high tariffs had based their argument largely on the protection of infant industries.[59] He considered the core of the protectionist theory from then until after 1900 to be safeguarding American labor from cheap foreign competition. But the theory was modified again, with the supposedly ideal tariff now to equalize foreign and domestic costs of production—"plus a reasonable profit for the domestic producer."[60] The cost criterion was scarcely as acceptable as the others. It was an "exploded and repudiated economic fallacy," it was "discredited by the best economic thought," and it was too "vague" to serve as a formula.[61]

[56] *Ibid.*, Dec. 22, 1920, pp. 631, 634; *ibid.*, Dec. 19, 1925, p. 1183.

[57] *Cong. Rec.*, Dec. 22, 1920, pp. 631, 634, 635; *N.Y. Times*, May 7, 1922, VII, 3:1; *Cong. Rec.*, Feb. 15, 1927, p. 3898.

[58] *Cong. Rec.*, Dec. 6, 1932, p. 65; see also *Press Releases*, May 6, 1933, p. 312.

[59] Around the turn of the century, when Hull first entered Congress, the two major arguments of protectionists were the pauper labor argument and the infant industry argument. The former remained popular all through—and beyond—the period of Hull's congressional career. But, except for some discussion in the 1921-22 debates concerning the "war babies," the infant industry argument was of very little significance in the postwar debates.

[60] *Cong. Rec.*, Dec. 22, 1920, p. 635. The cost-equalization criterion was mentioned in congressional tariff debates of the 1890's; it was first presented in a party platform by the Republicans in 1904; it first played an important rôle in a tariff debate in 1908-09; and it was embodied in the tariff acts of 1922 and 1930. Although not until 1928 did the Democrats espouse the criterion—"the extreme measure of every tariff rate"—in a platform, in fact some supported it as early as 1909. In 1928, the Republicans, keeping one step ahead of their opponents, conceived the "true" principle of protection to be the equalization of "competitive conditions."

[61] *Ibid.*, Aug. 13, 1912, p. 10835; *ibid.*, May 13, 1929, p. 1212.

However, virtually the only concrete objections Hull raised to the principle were administrative, not economic: it was impracticable to ascertain the pertinent costs.

The Competitive Tariff. Over the years, the respective stands of the two major political parties on the tariff gradually changed, with both tending to support higher and higher rates, and with the distinction between the party platforms becoming blurred. However, Hull persisted in trying to make clear "a vast, irreconcilable and well-defined difference in attitude" between the parties on this issue.[62] The Republicans, he said, nominally supporting the cost-equalization formula, were following a policy of extreme nationalism, consisting of a virtual embargo on all imports conceivably competitive.[63]

The Democratic position, as defined by Hull, did not embrace immediate free trade. His complaint against the Republicans was that they advocated, "not moderate protection, not reasonable protection, or sensible or practical protection, but embargo protection."[64] Although he criticized the vagueness of the Republican tariff criterion, he offered no precise formula for the Democrats.[65] Nevertheless, he frequently contended that his party favored a "moderate or competitive tariff for revenue."

The theory of the competitive tariff was not comprehensively elaborated in any single address, but it seemed to include the following elements: the fundamental justification for the tax was to provide government revenue,[66] with little or no regard for protection of domestic industry; while American producers should be able to expect a reasonable

[62] In 1931, a *New York Times* editorial remarked that Hull "is the last survivor of a great party tradition. . . . The party tradition before which he burns the lone lamp of worship is that Democrats have a clearly marked position on the tariff as contrasted with the Republicans." May 17, 1931, III, 1:2.

[63] *Cong. Rec.*, June 9, 1911, p. 1811; *ibid.*, Mar. 2, 1929, p. 5163.

[64] *Ibid.*, May 13, 1929, p. 1204. Even under a tariff bill which he could support, "drastic or abnormal imports against an efficient industry . . . would be safeguarded against" (p. 1208)—which raises the unanswered question of what Hull considered to be an "efficient" industry. See *Press Releases*, May 6, 1933, p. 314: Hull's policy "does not contemplate no tariffs, nor even low tariffs, but a reasonable, moderate, decent level of tariffs, in lieu of existing rank and wild excesses and discriminations."

[65] Indeed, he stated that until "the first long step" had been taken toward a liberalization of commercial policy, the problem of deciding on exact rate formulas was not pressing. Once production costs were lowered and foreign markets enlarged, "tariff demands will be modified, the rate basis will be different and easier of determination." *Cong. Rec.*, Jan. 3, 1929, p. 1073. Later, he added: "Naturally, as domestic industries become self-sustaining, tariffs should be correspondingly reduced, with the view to their ultimate removal, especially when there arises substantial exports and no material competitive imports." *Ibid.*, Mar. 2, 1929, p. 5163.

[66] It was not Hull's desire to put great reliance upon customs receipts to meet the government's needs; he preferred an income tax. Hull was the main architect of the income tax act adopted during the first World War.

profit, they were not warranted in complaining about fair competition; there would be no tariff shelter for monopolies and extortionate price policies; however, no efficient or economically justifiable industry should be endangered by abnormal imports;[67] the free list generally should include essential imports, commodities not produced here, and things which this country mainly exports; maximum rates should be placed on luxuries.[68]

Most-Favored-Nation Principle. After tariff rates were determined, on whatever basis, it was Hull's belief—although not often stated—that they should be generalized under the unconditional most-favored-nation clause. He was unsure of his understanding of the principle in 1919, but thought that it was "generally agreed" that adoption of the clause by all commercial nations "would remove virtually all kinds of discrimination in international trade."[69]

During the early part of his tenure as Secretary of State, Hull reaffirmed his support of the unconditional form of the clause and expressed hope that the United States policy of nondiscrimination and lowered trade barriers would induce other nations to follow a like course. He added that the chaotic economic situation might make necessary qualifications or exceptions to the favored-nation policy, mentioning specifically possible multilateral treaties the benefits of which would not be automatically generalized to nonsignatories who did not subscribe to the policy of the agreement.[70]

[67] "Competitive tariff rates do not contemplate destructive rates where existence of a business is justified economically, but rates competitive and designed to prevent monopoly and to assure reasonable competition in the domestic markets." *Cong. Rec.* Dec. 22, 1920, p. 635. He thought that allowing competitive imports to the extent of five to ten per cent of domestic production would prevent monopoly. *Ibid.*, Apr. 14, 1926, p. 7474.

[68] *Ibid.*, June 9, 1911, pp. 1811, 1812, 1815; *ibid.*, Mar. 11, 1924, p. 3947; *ibid.*, May 13, 1929, pp. 1202, 1208.

[69] *Ibid.*, Feb. 21, 1919, p. 3957. While colonial preferential arrangements were in violation of the most-favored-nation principle, he was reluctant to make a blanket condemnation of them. Nevertheless, in the interests both of commercial nations generally and of the colonies involved, the principle should apply to the fullest extent possible. *Ibid.*, Feb. 21, 1919, p. 3958. In 1916, two subjects he thought should be considered by an international trade conference (see above p. 107 and note 32) were "the permanent preservation of the principle of unconditional most-favored-nation treatment" and "as to colonies and a mother country, to either discontinue, or to adopt a broader and more liberal, operation of preferential tariffs and other kinds of preferential treatment." National Archives, State Decimal File 1910-29, 600.0031/2, letter from Hull to Secretary of State Lansing, Feb. 16, 1916.

[70] Department of State Files, A/LS 611.0031/561, memorandum by Hull of conversation with Minister of the Irish Free State, Sept. 21, 1933; *ibid.*, 611.003/2980, memorandum by Hull of conversation with Minister of Czechoslovakia, Mar. 1, 1934. Such a restricted interpretation of the rule of equality was included in the proposal Hull submitted at the close of the London Economic Conference and also in his resolution adopted by the Montevideo Conference in 1933.

At least as early as January 1929, Hull said that the United States could have utilized, as it could yet, the tariff bargaining method, based on the unconditional most-favored-nation clause, to supplement unilateral action to lower excessive tariffs.[71] And in late 1931, he discussed with the State Department the desirability of legislation authorizing executive reciprocal trade agreements, to be binding unless vetoed by Congress within six months.[72]

V. *Tariff-Making Procedures*

Republicans and the Tariff Interests. Hull astutely pointed out that high-tariff beneficiaries encouraged others also to strive for protection, for while tariffs raised living and production costs for everyone, common strategy "insures wider support for the general scheme."[73] But the protective system could be expanded and perpetuated only through political power, and it was the Republican Party which did the bidding of the tariff interests. Hull bitterly accused Republicans of exchanging tariff benefits for campaign contributions; indeed, this unholy alliance had gone so far that these special groups had become the dominant element of the party.[74] The mechanism by which the tariff beneficiaries virtually wrote their own rates included the lobbying system, which "presents a continuous round of political and legislative debauches with graft aforethought."[75]

Tariff Boards and Commissions. From the foregoing, it might be supposed that Hull would have supported from the beginning the establishment of some kind of tariff commission to make studies of, and formulate recommendations on, commercial policy. However, he strongly opposed the Taft Tariff Board (1909-12). He claimed that the Republicans gave nominal support to the idea of the Board (as to the Tariff Commission of 1882) only for ulterior reasons of political expediency, to avoid immediate lowering of the tariff. An impartial board would recommend tariff reductions, but it was ridiculous to imply that

[71] *Cong. Rec.*, Jan. 3, 1929, p. 1073; see also *N.Y. Times*, May 30, 1931, 1:8.

[72] Department of State Files, A/FU 611.0031/375, communication from Wallace McClure to C. M. Barnes, both of the Treaty Division, concerning a conversation of the former with Hull, Oct. 31, 1931: "He [Hull] seemed to feel strongly that only by executive action without confirmation by Congress could the reduction of the American tariff, which he urgently advocates, be made the instrument of reducing at the same time the tariff of other countries which impede the exportation of American goods."

[73] *Cong. Rec.*, Apr. 14, 1926, p. 7472.

[74] The Republican party was "the pliant tool, the shield bearer, the toady, the lackey, the flunky of protection and the trusts" in "the most corrupt partnership between politics and vested interests in American history." *Ibid.*, June 9, 1911, p. 1812; *ibid.*, Apr. 16, 1929, p. 52.

[75] *Ibid.*, Apr. 14, 1926, p. 7472; see also *ibid.*, May 13, 1929, pp. 1202, 1205.

"only a Tariff Board knows how to subtract." Although Congress could profitably utilize expert assistance, it was more capable than a board to deal with the tariff. Board investigations were too slow, and both political parties were likely to ignore their findings, in any case.[76]

He was more favorably disposed toward the Tariff Commission established in 1916, and in 1920 appealed to the House not to attempt a general tariff revision before the Commission completed a "full investigation of all the essential facts."[77] While he continued to support the idea of an unbiased commission, he deplored the alleged factionalism, partisanship, and subservience to executive pressure of the body under Republican administration.[78]

Conclusion

It would be unfair to make the general condemnation that Hull's conclusions were usually correct—but for the wrong reasons. Nevertheless, deficiencies in his analysis have been apparent. Some matters basic to the theory of international trade were not expounded, and topics included in his discussion usually were incompletely examined. Intuitive conviction and frequent, enthusiastic reiteration generally did duty for rigorous analysis. It is fortunate that his intuition typically was sound.

Hull remained consistent and steadfast not only in Congress, but during his tenure as Secretary of State—and such consistency required no little political courage and moral conviction. Moreover, in their prolific defense of the Trade Agreements Program prior to the second World War, representatives of the State Department followed very closely the views of the Secretary. And in their main outlines, Hull's tariff views when in the cabinet were essentially the same as those he had expounded from the time he entered Congress in 1907. Thus, the ideas on trade and international relations generally which we have reviewed furnished the philosophy of much of America's foreign policy during the New Deal period.

NATIONAL INCOME AND PRODUCT OF THE UNITED STATES, 1929-1950[1]

By L. R. Klein*

The National Bureau of Economic Research in one of its most successful projects gave the United States a national income. The National Bureau's contribution was truly developed and fashioned into a highly refined product by Simon Kuznets. It has been a healthy development to follow up the initial research by transferring the main part of national income measurement from a relatively small, independent organization with limited resources to a government bureau whose comparatively tremendous resources can be mobilized to the continuation of periodic estimates of national income and to the improved precision of the resulting statistical series.

The National Income Division of the Department of Commerce has actually done more than remain as the custodian of our national income. They have introduced numerous modifications and refinements of concepts and techniques. For the first time since Kuznets presented us with the underlying details in his great 2-volume work, *National Income and Its Composition, 1919-1938*,[2] we now have the relevant facts concerning the preparation of current national income data. The statistical series of the National Income Division are now regarded as "official" data and are the most widely used for the period since 1929. For many years, we have been using these data without knowing much about them other than the circulating rumor that they are quite precise. It is our good fortune to have the lucid and frank presentation contained in the volume under review in order that we may all judge this important fund of information with the greatest of care.

The Commerce Department's document presents a review in statistical terms of the growth and fluctuations of the U. S. economy since 1929, the conceptual framework of national income statistics, the sources and methods of estimation, constant dollar estimates of national product, and numerous statistical tables bearing the fruits of the

* The author is research associate of the Survey Research Center and lecturer in economics, University of Michigan.

labors. The major contributions are the previously mentioned frank statements about the procedures involved and the addition of several new features such as imputed rent, imputed interest, the treatment of government interest as a transfer, the use of retail sales statistics and other data for improved estimates of consumer expenditures, the revaluation of inventories by type of accounting systems used, and the constant dollar estimates of national product. Some of these features were already incorporated in the 1947 revision of the national income data. In addition, the authors provide well-reasoned judgments on the comparative reliability of their various series. They are able to recognize limitations of their results as well as innumerable virtues.

The statistical review of economic developments since 1929 is ably done within the confines of the data contained in the volume at hand. The presentation is weak, however, in failing to take account of the rôle of exports, under the European Recovery Program and also through more traditional channels, in sustaining economic activity in this country since 1948. In restricting themselves to the use of their materials alone, the authors are not able to draw on the existing body of financial, price, wage and other statistics that would enable them to give a more rounded view of the total economy. This part of the volume shows clearly the narrow scope of the aggregative national income statistics.[3]

The most important parts of the volume are, however, those having to do with the conceptual framework, the sources, and the methods of estimation. The conceptual framework conditions the orientation of the program of the National Income Division and consequently has a great bearing on the final results. The concepts are stated clearly and unambiguously. On this account there can be no criticism, but the arbitrary nature of the decisions that have been made becomes obvious. Moreover, the rationalization of several of these decisions is painful to the reader.[4] Many of the rationalizations could have been left unsaid. The important thing is that we be provided with a clear statement of the calculations made. In some cases decisions are admittedly based on long-standing traditions in the field of national income measurement. With these there should be no quarrel as long as the position is openly stated.

[3] In contrast, the diagnosis of economic activity given in the periodic reports of the Council of Economic Advisers is much more comprehensive and points up the need for drawing on numerous statistical sources outside the materials of the National Income Division in order to present an adequate picture of the situation.

[4] In discussing imputed income, the authors say that lodging furnished domestic servants is not imputed because "it is felt that as a general proposition, they do not regard the lodging furnished them as an addition to income." Perhaps repetition of the quoted phrase makes the authors feel better about their decision on imputations. It gives me no comfort.

The premise from which the authors commence their analysis is that the central objective is to measure total output. In making a plea on behalf of many professional economists and statisticians who rely heavily on the data produced by the National Income Division, I would argue that this is not a satisfactory central objective. I would put forth the alternative conceptual framework that the central objective should be to develop a comprehensive and detailed system of social accounts. The comprehensiveness and detail should be as great as quality standards and resources permit. Historically, modern developments have been concerned with the estimation of various aggregates all subsumed under the generic term, national income, but in view of present knowledge do we still want to set out from this starting point? It seems that the requirements of the present are for a set of social accounts from which a variety of problems can be studied, including those for which measures of national income are specifically designed.

There is not, of necessity, a conflict between the construction of particular measures of aggregate output and the broader concept of social accounting. The complaint registered in these pages is simply the impression that aspects of social accounting may have been retarded in development and that the presentation of arguments in *National Income* has been strained by the excessive attention paid to national income totals.

Let us consider, as an example, the treatment of corporate profits in the national income estimates of the present volume. The authors argue that corporate profits, as a component of national income, should be reported before rather than after taxes; hence their national income estimates include corporate profits taxes as a positive component. In order to justify the inclusion they argue that national income should remain invariant under changes in tax structure alone (*e.g.*, a shift from excise to corporate income taxes of equivalent yield), and if corporate profits taxes are not shifted forward, they will obtain the desired invariance by their treatment. By the same line of argument, they point out that indirect business taxes should be excluded from national income if they are wholly shifted forward.

Parenthetically we mention that if the invariance argument is taken to its logical conclusion, a number of new problems are raised in national income estimation. Should the value of national income vary simply because a woman shifts from doing her own housework to doing housework for someone else?[5] Should construction expenditures (not aggregate output) be different if a person makes an addition to his home without a permit instead of with a permit?

[5] Norwegian estimates of national income have been forward-looking in that they have included the value of housewives' services.

The specific treatment of corporate income and indirect business taxes is not necessarily subject to extreme criticism; perhaps the aggregates so defined serve many useful purposes. It is the peculiar rationalization given in the Commerce Department's document that is so annoying. In practical applications there are some situations in which statistics of profits after taxes are urgently needed while other situations call for statistics of profits before taxes. In studying capital formation in the trade cycle we often want to use the former concept, and in studying the ability of corporations to increase wages we often want to use the latter concept. Statistical data are presented in the national accounts of the Department of Commerce in such form that analysts can easily shift from one profit variable to the other; for this reason their present practices unadorned by rationalizations would be acceptable. In the treatment of other items the situation is not as favorable since data are not easily accessible for altering the published concepts. Property taxes on owner-occupied residences cannot, without additional tabulations, be shifted to personal from business taxes. It is not altogether clear that the decision of the National Income Division to regard ownership of residential housing as a business in which one sells services to oneself is useful in business cycle analysis nor should expenditures on new residential construction by owner-occupiers necessarily be regarded as capital formation rather than consumer expenditures. Many students of business cycles have argued that new light may be shed on behavior patterns if statistics on owner-occupied residential housing are grouped with consuming rather than investing or business activities. A flexible system of social accounts with adequate detail permitting users of the data to group figures into a variety of aggregates to suit purposes as they arise would be much more useful than the present body of statistics which are rigidly aimed at construction of a few arbitrary aggregates.

In my own econometric studies, I have never found it possible to accept data in the form published by the Department of Commerce. There has always been a necessity to adjust and recombine materials by drawing on unpublished records. The same is true of numerous other research workers using different techniques. A reorientation of the programs of basic data gathering organizations to meet the needs of research is required, and the National Income Division of the Department of Commerce, so closely wedded to the time-honored objective of measuring total output, is one of the most important places in which a changed outlook would be rewarding.

Specific concepts, in addition to the example of corporate profits and residential housing used above, raise problems of disagreement. The more significant of these shall be taken up in turn:

Depreciation. The practice of the National Income Division is to value depreciation estimates in accounting prices (book values essentially) in all sectors except agriculture, where they use the replacement cost estimates of the Department of Agriculture. This gives a curious mixture of prices, one that is most unsatisfactory for using data from the social accounts to study capital growth. If social accounts are to assist us in measuring welfare, in some sense, they must surely provide us with material for estimating net investment, the change in the stock of productive capital. Numerous other uses of net investment and depreciation statistics also arise. Pessimistic statements are made by the authors about the possibility of revaluing depreciation, especially with limited resources, but this is such an important item that other things should be sacrificed in order to devote more efforts in this area. The works of Fabricant[6] and Goldsmith[7] have broken the ground for the Department of Commerce. I would venture the personal opinion that revaluation of the present estimates from materials now available without any substantial refinement is to be preferred to the procedure now used in the social accounts. This opinion is offered after having considered the comparative accuracy of other items, say professional income, which are considered reliable enough for inclusion in the accounts. Moreover, some components of depreciation are not available from accounting records (residential real estate is a major example), and the Department of Commerce must prepare their own estimates. They could equally well prepare these in terms of replacement instead of original costs, and have another large component in the same price system as agricultural depreciation.

It is even worth arguing that book values should be entirely discarded. Statistics of wealth, annual gross purchases, prices, and estimated useful life could be combined to give an entirely independent set of estimates for those components now based on accounting records. In many respects, these estimates would be superior to those contained in accounting records. Aside from the price level problem, there is substantial suspicion that business accounting reports are geared to other objectives than measuring capital consumption in their depreciation practices. The National Income Division can argue that estimates of gross national product are unaffected by the valuation system for depreciation, but this argument carries little weight since so many other important items are directly affected.

If depreciation is revalued, profits must be changed in a compensa-

tory fashion; hence book profits would no longer be the basic figure in the national accounts.

Government interest. Formerly, government interest payments like other interest payments were regarded as factor shares and included as part of national income. With the growth of interest payments on an enormous war debt, the National Income Division correctly recognized a distortion in national income statistics. Their reaction has been to exclude all government interest payments from national income and to regard the government's contribution to production to be measured only by wage and salary payments. Fortunately the published accounts list government interest payments separately so that analysts can easily revise the figures to include government interest payments if they so desire. However, we might ask more of our social accounts. In particular, a more careful accounting should be given of the entire government sector. As Colm and Kuznets have pointed out, some government services are intermediate products, while others are final.[8] According to their position, the production of all government services (or goods) would have to be classified as intermediate or final with the former excluded from national income and the latter included. Some wage payments would fall in one category and some in another. We may forget about government interest payments as a component of income and focus attention on the services yielded by government capital. Unlike private bonds, government securities are not issued on a self-liquidating basis; therefore government interest payments should be treated exclusively as a transfer in this more detailed accounting scheme. The services of government capital must, like wage payments, be classified as intermediate or final, with only the latter included in national income.

The valuation problems for such treatment of government accounts are overwhelming; therefore a pragmatic scheme like that adopted in the Canadian national accounts may be suggested as a more desirable alternative than the approach used now by the Department of Commerce. The Canadians attempt to distinguish between productive and unproductive government interest payments. In this country state and local debt has not been directly used for war finance and should be included in national income. Federal government interest payments on nonwar debt could also serve as a rough indicator of services yielded by government capital. In spite of the estimation problems involved, attempts to obtain more meaningful figures would be superior to the

Kuznets "Government Product and National Income," *Income and Wealth,* Series I, ed. by E. Lundberg (Cambridge, Bowes and Bowes, 1951). Colm cites A. C. Pigou. *A Study in Public Finance* (London, Macmillan, 1928), for an earlier expression of this idea.

present biases. These remarks on government interest payments are mainly concerned with the use of national income statistics for the measurement of welfare, and while we pursue this aim, we must not lose sight of the multipurpose aspects of social accounting.

Disposable income. The usefulness of this concept is largely related to estimating economic behavior, particularly spending and saving behavior. It is more true in this case than in others that a variety of concepts are needed to deal with problems as they arise. Even for the familiar and popular problem of studying patterns of consumer expenditures it is not clear how we should define disposable income. The Department of Commerce would do well to provide us with material for estimating several concepts and should attach no intrinsic significance to its own definition.[9]

Licenses and fees paid to governments are deducted, like personal taxes, from income payments in calculating disposable income. On the other hand, bridge and road tolls, which are like many licenses and fees in that they are discretionary personal outlays, are treated as consumer expenditures. In general, we might argue that some deductions now made from personal income to get disposable income should be transferred to consumer expenditure. Other items which should experimentally be left in or out of disposable income are contractual obligations, capital gains, and corporate saving. The last mentioned item is, of course, easily available in the present arrangement of accounts, but the other two are not. Capital gains are religiously excluded from national income statistics, but this practice is hardly acceptable if emphasis is shifted from the objective of estimating aggregate output to the preparation of useful social accounts. The authors are by no means unaware of these problems but they make little contribution toward their solution.

Unilateral transfers abroad. In the postwar period, the United States government has made large cash grants to foreign countries for purchases of its domestic goods and services. The method of entering these transactions in the national accounts is, by the authors' own admission, not very satisfactory. In addition, the description of their procedures is not sufficiently elucidating to enable analysts using data in the accounts to avoid pitfalls. It is almost necessary to supplement the present document with a clarifying article by W. Salant[10] in order to be certain of the interpretation of published data.

[9] The discussion between C. L. Barber and S. A. Goldberg is instructive in this respect. C. L. Barber, "The Concept of Disposable Income"; S. A. Goldberg, "The Concept of Disposable Income: A Reply," *Canadian Jour. Econ. Pol. Sci.*, 1949, XV, 227-29 and 539-42.

[10] W. Salant, "International Transactions in National Income Accounts," *Rev. Econ. Stat.*, 1951, 33, 304-15.

In effect, unilateral transfers are recorded in three places of the accounts. In the first instance, when the cash credit is made available to foreign countries, government expenditures are increased by the amount of the transfer. Simultaneously imports, a negative component of national product, are increased by the same amount. On balance, the transaction has no effect on aggregate output, but it does swell the statistics of government expenditures and imports for anyone who wants to use these data in separate analytical studies. In the second instance, when goods and services are purchased with these funds by foreigners, exports are increased. This transaction may not occur in the same accounting period as the initial cash transfer. For many purposes, this entire transaction is a government expenditure, pure and simple, in which goods and services are given to foreign countries. They should be entered in government purchases of goods and services and not in other accounts. However, a separate account with transfer items, suggested by the authors, would be useful.

In suggesting that various controversial or debatable items whose conceptual basis is not clear to all theoreticians be given alternative treatment by the National Income Division, we do not lose sight of the fact that they are a responsible government agency and are prevented from engaging in certain more speculative types of research. Yet more satisfactory treatment of key items such as depreciation, government interest, and disposable income is an urgent minimum task and, as argued above, not subject to larger margins of error than will be found in other items which are voluntarily published. A lowering of quality standards would not be entailed in revising the estimates of the items discussed here.

We have come to look upon the statistics of national income in the United States as the most reliable in the world, in fact nearly as the absolute truth. Reports are periodically released in the popular press about movements in national income as though the data contained in them were facts. The true character of these data as *estimates* is brought out in Part III of the volume. My impression, from reading this section of the report, is that I had previously overrated the accuracy of the data. My faith is now shaken and I am able to take a more realistic view, surely that of the authors. The comprehensiveness and detail of the tasks involved in the intricate estimates are overwhelming; diverse sources are combined for proxies, benchmarks, extrapolations, interpolations, and other indirect devices. We can only congratulate the National Income Division on performing their estimating tasks as well as the available data permit and on explaining this complex operation to users of their material.

A brief summary reviewing the main techniques used for each major

component of income and expenditure may be helpful in forming an impression about the methods and their reliability.

Wages, salaries and supplements. This series is primarily based on payroll statistics. Sample surveys are used for farm labor and a rough estimate from wage and employment data is used for domestic servants. On the whole wages, salaries, and supplements are reliably estimated. They are probably the most accurate of all major income components and account for a large share of total factor payments.

Unincorporated and professional enterprise. Personal income tax returns contain some accounting data for unincorporated business, and serve as the main source. Much more detail is needed than can be gleaned from the statements that are filed on the returns. The methods of adjusting for persons not filing returns are inadequate, especially in depression years, when there are likely to be a number of businessmen receiving low or negative income. Farm income is estimated by the Department of Agriculture on the basis of mail questionnaire surveys, censuses of agriculture and crop reporting schemes. Professional income is also determined from mail surveys, but the indicated response rates are extremely low, 15 per cent of the mailing on the average. In addition, there is serious doubt whether professionals are willing to report the full amount of their income to any government agency. There are strong reasons to question the accuracy of income data in the entire sector of unincorporated enterprise.

Rental income of persons. Rental income of business is included under income of unincorporated or incorporated enterprise. Individual income tax returns are used to establish benchmark estimates for net rent receipts. Census statistics, samples, and the rent index are used for interpolation or extrapolation. The estimation of imputed rent on owner-occupied homes is based on essentially the same sources. Rental income from farm property is separately estimated by the Department of Agriculture. The rent series, like the series on income from unincorporated business, is lacking in reliability.

Corporate income. Corporation income tax returns supply the basic data for estimating corporate income, the sum of dividends and retained earnings. Seemingly this series is accurate, but the accuracy applies only to book values. There are many reasons to believe that reported earnings are not the true earnings figure we want for many applications of social accounting data. In so far as the deviation of earnings figures from economists' norms are balanced by deviations in the opposite direction among other components of national income, the measure of aggregate output will be unaffected. Even book-value figures, however, present difficulties for the National Income Division. They must make adjustments for audit, capital gains, foreign dividends, mutual cancel-

lation of domestic dividends, and other items. In general book-value profits rank high in reliability among income components.

Interest. Corporate and government interest are well covered, the former in corporate income tax returns and the latter in government financial reports. Income tax data, consumer credit statistics, and miscellaneous sources are drawn upon for the estimate of the remainder, a major component of which is imputed interest rendered by financial intermediaries. The curious practice is followed of not including interest on charge accounts or installment debt other than that on automobiles. Except for corporate and government interest, this factor share is probably not reliable.

Personal consumer expenditures. Expenditures on commodities are estimated mainly by Kuznets' commodity flow method until 1939 and extrapolated from that point by indexes of retail sales. The commodity flow method starts from the value of production, allocates output among finished and unfinished producer or consumer categories, and corrects for inventories, distribution charges, and retailers' markups. This procedure involves a complex series of steps, each of which requires judgment and is a potential source of error. Errors in allocation of output between consumer and producer goods are not always offsetting in the estimation of total output. Automobile purchases and some other items are estimated by the retail valuation method (multiplication of price indexes and quantity data). The data on used cars are rough, while the data on new cars contain an arbitrary separation between producer and consumer goods.

Expenditures on services are estimated from annual reports of railroads and utilities; censuses of housing, business, and agriculture; sample surveys on professional incomes; and other sources. Some of these sources provide scanty information, but even in the case of supposedly accurate statistics like those of rail passenger travel, a separation must be made between personal and business expenditures. Errors in making this separation are not offsetting for the measurement of aggregate output.

There are undoubtedly errors in the consumption component of national expenditures, but the National Income Division must be praised for the elaborate detail they have presented on types of expenditures and the complete reliance on direct information for this strategic magnitude.

Construction. Public reports, building contracts let, and building permit records are the main sources for estimating construction. Data from the F. W. Dodge Corporation cover only states east of the Rocky Mountains and must be extended to the entire country. Permit data traditionally understate the value of construction and must be revised

upwards. In addition there are problems in estimating construction in nonpermit and farm areas. Expenditures on additions and alterations are significant in total construction outlays and are based on permit statistics, yet permits are not issued for many such expenditures. On the whole, construction expenditures rest on reliable bases, but they leave room for definite improvement.

Producers' durable equipment. The commodity flow method is used for this item in a similar fashion to its use in estimating consumption, with many of the same possibilities of error. Motor vehicle data are valued directly from price and quantity series, while other types of equipment, such as rail equipment, are estimated directly from industry sources. A decent level of accuracy is probably achieved.

Inventory change. Inventory data are notorious for providing pitfalls for national income statisticians. The basic problem is to revalue the change in book value data in order to measure the value of the change instead of the change in value. The National Income Division has devoted careful effort to this task. They have tried to classify book data by Lifo or Fifo valuations and used adjustment techniques appropriate to each valuation. The data on corporate inventories come from corporate income tax returns, but the data on other inventories come from censuses and inadequate individual tax returns. The job is undoubtedly done with the utmost care, but the result cannot be marked with a very high degree of reliability simply because of the lack of necessary basic data.

Net foreign investment. Foreign commerce statistics on goods and some factor payments are undoubtedly quite satisfactory. These make for accuracy in the estimation of the foreign balance. Remittances, travel, and tourist expenditures seem weak, however. Data on remittances cover only a limited number of financial instruments. The samples of passengers described to determine consumer expenditures on transportation and tourism cannot be said to inspire confidence.

Government expenditures. The receipts and expenditures of the federal government are soundly reported in budgets. A series of adjustments must be made to eliminate transfers, subsidies, and other items. Expenditures on goods and services are finally estimated as a residual. Some components of goods and services are, however, directly estimated. State and local data are less satisfactory and pose some problems in the conversion from fiscal to calendar year accounting. Notwithstanding these adjustments, the series on government expenditures is highly reliable.

Personal savings. The subtraction of consumer expenditures from disposable income yields a residual estimate of savings. Like all residual estimates, the savings data permit diverse errors to enter, and the

resulting reliability is low. We do, however, obtain direct estimates of savings from data published by the Securities and Exchange Commission, and these could possibly be used for many purposes in lieu of the estimate of the National Income Division. A useful table (6) included in the document under review reconciles the liquid savings estimates of the S. E. C. with the residual estimates contained in the national income accounts. In this reconciliation, data on many specific items useful in deriving alternative aggregative concepts are, incidentally, made available.

The appraisal in this review of components of income and outlay by relative degrees of accuracy largely follows the listing given in *National Income*. This type of analysis is useful for several applications, and the technicians who compile the material are certainly in the best position to furnish a listing in the proper order. Some econometric applications have taken into account the existence of errors of observation, but in practice it has not been feasible to determine the relative error variances of the series used. The authors do not provide us with error variances, but they do take us a good step nearer this end. It is possible that useful econometric results could be ascertained from the type of information that is available to the national income statistician. It is hoped that work on the assessment of relative errors will be pushed in future efforts so that we may accumulate even more useful measures than crude rankings through experience.

A possible measure of reliability, in terms of internal consistency, in the estimation of components of income and expenditure is the size of the statistical discrepancy, the divergence between the estimates of national income and national expenditure or product after certain reconciling items in one series but not the other are taken into account. The size of the statistical discrepancy is often cited in favor of the accuracy of the national income estimates of the Department of Commerce. While some encouragement can be taken from consideration of the magnitude of the discrepancy, we cannot remain complacent over the fact that the figure is as large as $3-5 billion in some years. Percentagewise in terms of gross national product this seems to be small, but it represents the yearly output or income of many persons. It is definitely not negligible. As is well known, individual key components can be grossly in error, while the national income and expenditure accounts nearly balance in total. More work is called for in the analysis of this term. What are its time-series properties? Does it behave like a random series?

Throughout the discussion of the methods used in compiling the main items of the social accounts it was observed that sample surveys are used, in some cases to extend benchmarks and in others to establish

basic series. The different surveys used vary in quality, but among the poorest are some based on mail questionnaires. The response rates are often extremely low, leading one to doubt the usefulness of the collected material for calculations in a field where aspirations for accurate measurement are high. The most obvious suggestion, undoubtedly entailing additional expenses, is to replace these surveys with personal interview surveys based on carefully selected samples.

It is interesting to consider a number of ways in which well-conducted field surveys could be further exploited as a means towards filling in some of the largest gaps in the social accounts. A fruitful area in this respect is the unincorporated enterprise sector. Personal interviews could be conducted to ascertain prevailing accounting practices and to collect more detail than is reported in personal income tax returns. A very important item for analytical studies is a measure of unincorporated business saving to parallel the concept of corporate savings. The accounts in the Commerce Department's document do not provide information on these entrepreneurial savings, and direct personal interviews seem to be practically the only feasible source for obtaining reliable estimates. On the income side of the accounts, various subdivisions can be made into farm income, entrepreneurial income, wage income, etc. On the expenditure side corresponding divisions cannot be found for matching in analytical studies on expenditure behavior. Farm spending and saving or entrepreneurial spending and saving are not separately given, and survey statistics seem to be the logical source for rounding out the accounting system in this respect. It will not be satisfactory to prepare isolated surveys to attempt to provide some benchmark estimates where no others exist. We really need a repetitive flow of surveys to supply a continuous record of various basic data.

The structure of our national accounting system for the most part follows the well-established lines set out in early national income estimates. A clearer picture of the national economy is often obtained from accounting structures more closely resembling those that have been widely and successfully used in operating private enterprise. If the economy is split into groups such as households, business firms, financial institutions, government, and the outside world, we can envisage income statements and balance sheets for each group. The income statement consists of receipt and expenditure items that are components of the present national accounts. Double entry arrangements into income statements or receipt-expenditure accounts give good views of the operation of each sector and also of their linking together in the circular flow mechanism. Either conventional balance sheets of assets and debts, or statements of changes (over the accounting period) in these capital items are needed in addition to the flow statements on receipts

and expenditures. The Dutch social accounting system laid out in this form has achieved great elegance in presentation and has proved quite useful in economic planning.[11] The schemes of Richard Stone,[12] based usually on the British economy have been even more elaborate but have the same general nature of giving a unified accounting treatment to the entire system. Less preoccupation with certain arbitrary aggregates is perhaps the reason that the accounting presentation abroad has been developed to a more refined state than in this country. We may be pleased to observe that in the present volume a series of tables is given in which current income accounts are presented for the business sector, the personal sector, government, and the rest of the world. These accounts are given on a highly aggregative basis for the year 1950. A vigorous research program designed to reveal more detail in a larger number of sectors would be a more suitable objective of national income research than that of measuring aggregate output in some sense. The capital account in the framework of the Commerce document is very gross; it simply shows the mutations in less than a dozen asset-liability items.

The constant dollar series on national product represents one of the major new contributions of the present volume. The National Income Division has performed this job carefully, deflating each of several detailed components by the corresponding price index. I can fully sympathize with the authors' remarks that various alternative experiments in weighting and other details have had little effect on the final result. In fact, much cruder deflating methods used by Harold Barger and myself on the same current price data have produced nearly the same result for the valuation of gross national product in 1939 dollars. Nevertheless it is important to have the job done by detailed components in an agency that can afford the resources because periods could arise in which more refined calculations would show truer results than would crude methods.

The revaluation to constant dollars is carried out only for the product or expenditure side of the national income accounts. It is interesting to speculate on the possibility of similarly revaluing the income side. The components of the wage bill could be deflated by indexes of wage rates; components of rental income could be deflated by indexes of rent. The appropriate concepts are not clear for all income shares such as corporate profits, interest, entrepreneurial income, and other items that are not primarily formed as a product of market prices and quantities. Progress could, however, be made in the direction of revaluation of

[11] See, *e.g.*, *Central Economic Plan, 1952*, Appendices, Central Planning Bureau, The Hague, August 1952.

[12] R. Stone, "Functions and Criteria of a System of Social Accounting," *Income and Wealth*, Series I, ed. by E. Lundberg (Cambridge, Bowes and Bowes, 1951).

some major components of income. If the entire income side could be expressed in constant prices together with the expenditure side, we could construct a closed set of accounts in a constant price system.

By orienting ourselves in a social accounting framework and neglecting specific aggregates we could consider the problem of revaluing in each sector all debits and credits expressible as products of market prices or wages and quantities. Remaining items in the accounts, essentially balancing items such as profits and savings, could be revalued on a residual basis, as the difference between all other debits and credits in the accounts revalued to the constant price system. Ultimately, the complete set of revalued items could be combined into aggregates of national income, national product, and national expenditure.

Users of national income data who study trends and fluctuations in the economy will profit considerably by having the constant-dollar series of national product available to them. There are other tasks, yet undone, for which it would be appropriate to ask the National Income Division to allocate some of its resources in the interests of enhancing our knowledge of the economy. We have, on the one hand, Kuznets' annual estimates of national income covering the period since 1919 but not maintained currently in competition with the Department of Commerce and, on the other hand, the estimates discussed here for the period 1929 to date. Prior to the 1947 revision of concepts by the Department of Commerce there were available statistics, based on homogeneous concepts, giving a picture of the economy from 1919 to 1946. A new, and perhaps more careful, splicing of the two bodies of data is required for the study of various problems in the development of our economy by methods of time series analysis.

Quarterly data are available in the volume from 1939 to date. Barger[13] has published quarterly estimates for the period 1921-1938, and these too need to be carefully spliced with the current series. For many purposes of analysis, short-run data are essential and these should, if possible, be available for a continuous period of many years. The new quarterly estimates are quite aggregative, covering only the main components of national income and product. It would be desirable to have more detail forthcoming as a result of new efforts in the building of quarterly series. It should also be mentioned that the quarterly data are all presented in current prices. There is a present need for these data in constant dollars.

Although the quarterly series are the most important in several types of analysis, especially business cycle studies, they are unfortunately less reliable. The discussion on methods of estimation in the volume refer

[13] Harold Barger, *Outlay and Income in the United States, 1921-1938, Studies in Income and Wealth,* Vol. IV (New York, National Bureau of Economic Research, 1942).

only to annual statistics, and we know little about the inner character of the quarterly series compiled since 1939. There is need for a similarly revealing description of quarterly estimates—of interpolations, seasonal adjustments, the use of samples, etc.

The shifting of the burden of preparation of national income data from pioneering statisticians working in small research units to a large government agency has proved to be thoroughly desirable. The workmanlike job described by the Department of Commerce authors shows the advantages of this shift at the present stage of development of the subject. Accuracy of the resulting data has definitely been improved. We express our hope, however, that work in the subject will not become routinized; that statisticians both inside and outside the National Income Division will continue to bring new ideas to bear on the problems of social accounting.

COMMUNICATIONS

Population Growth and the Demand for Capital

In discussions of the stagnation thesis economists still disagree about the relative significance of a decline in the percentage rate of population growth and a decline in the absolute rate of growth. A number of supporters of the stagnation thesis attach a special importance to the absolute rate of growth apparently on the grounds that the acceleration principle is based on the absolute rather than the percentage rate of growth in final demand. Thus Benjamin Higgins states: "Speaking generally, the absolute rate of growth is the more important concept, and a falling percentage rate of increase is significant mainly as a harbinger of a later drop in the absolute increase. . . . For that part of the argument based upon the acceleration principle, the absolute rate of increase is clearly more important."[1] Similarly A. H. Hansen, after a reference to the long-run effect of the percentage rate of population growth upon capital formation, states: "The business depression in 1929 was the first one in our history in which a drastic decline in the absolute increment of population growth occurred. Now we all know that the acceleration principle in business cycle theory is based on the absolute increment of growth of final demand and not on percentage increase. Here was a wholly new factor that contributed to the severity of this depression."[2] Likewise, H. A. Adler states: "The reason for emphasizing the absolute increment in population growth with respect to the 1930 depression lies in the working of the acceleration principle."[3] The opposite view to this has been summed up by George Terborgh in his terse remark that, to say the absolute decline in population growth is more important than the relative decline "is like saying that a pound of growth on a dog has the same significance as a pound on an elephant."[4]

None of the writers who stress the importance of the absolute rate of growth state exactly why or to what extent the acceleration principle supports their argument. If their conclusions are based on a belief that this principle applies only to the case of absolute growth, they have fallen into an error. The acceleration principle can be applied either to a percentage rate of increase or

[1] "Concepts and Criteria of Secular Stagnation," *Income, Employment and Public Policy* (New York, 1948), p. 99. Higgins also notes certain circumstances where he believes that the percentage rate of growth is the more important concept.

to an absolute rate of increase in population or of final demand. Its basic assumption is that there is a fixed ratio between the level of income or consumption and the quantity of capital. It is true that textbook illustrations often state the principle in terms of absolute increments of final demand but this does not mean that it cannot also be applied to percentage increments. It seems more probable that these writers have been thinking of the fact that, neglecting replacement demand, an absolute fall in the volume of investment will occur when the absolute increments in final demand begin to fall. But the significance of this conclusion may be more limited than has been generally realized. Since there has been some confusion on this matter, it will be useful to state these relations more precisely. The application of the acceleration principle to the cases of absolute and relative growth in population will be considered in turn. For simplicity it will be assumed initially that the level of per capita real income remains constant. The effects of replacement demand are neglected throughout.

Let us suppose that population is increasing by equal annual increments which we will designate by p. Let k represent the amount of increased investment measured in dollars of constant purchasing power that is called forth by the addition of one person to the population. Accordingly, the total amount of investment due to the working of the acceleration principle in relation to population growth (hereinafter called population investment) will be $k \cdot p$ and this will remain constant as long as population continues to grow by equal annual increments. Now it is clear that if per capita real income remains constant the total national income must rise as the population grows. If savings are a constant percentage of income, the total amount of savings will rise also. Thus as the population grows at a constant absolute rate, population investment will become a successively smaller percentage of national income and of total savings. A gradually increasing percentage of the total investment required to offset current savings will have to come from other sources. Hence even when population is increasing by equal annual increments, there is need for a rising volume of investment from sources other than population growth if chronic underemployment is to be avoided.[5]

Let us now assume that population, instead of growing each year by constant absolute amounts, grows at a constant percentage rate which we will designate p'. Assume as before that the amount of investment called forth by the addition of one person to the population is k. Then, if we denote by P_n the population at the beginning of any year n, the absolute growth in population for the year n will be $p' \cdot P_n$ and the absolute amount of population in-

[5] This analysis has an application to a famous discussion in the literature of the acceleration principle. Ragnar Frisch has shown that under certain circumstances a decline in the rate of increase in consumer-taking need not lead to an absolute fall in the level of investment. This would be true if the rise in the replacement demand for equipment were sufficient to offset the fall in the expansion demand for capital equipment. But even in this special case Frisch's argument fails to note that the volume of net investment would fall and that the volume of gross investment, even though constant, would be a declining percentage of national income. See R. Frisch, "The Interrelation between Capital Production and Consumer Taking," *Jour. Pol. Econ.* (Oct. 1931), XXXIX, 646-54, and the discussion with J. M. Clark in subsequent issues.

vestment will be $k \cdot p' \cdot P_n$.[6] From this it follows that the ratio of population investment to national income for any year n will be equal to:

$$\frac{k \cdot p' \cdot P_n}{P_n \frac{(1 + p')}{2} y},$$

where $P_n \frac{(1 + p')}{2}$ is the population at midyear and y is the level of per capita real income. Since P_n cancels out of both the numerator and denominator we are left with an expression in terms of k, p', and y, all of which are constants by hypothesis. This means that, where population is growing at a constant percentage rate, population investment will remain a constant percentage of income. If, in these circumstances, saving is a constant percentage of income, population investment will absorb a constant proportion of total savings. It also follows from this expression that a decline in the percentage rate of population growth will cause the ratio of population investment to national income to decline.[7] One particular form of a decline in the relative rate of population growth is a population which increases by constant absolute amounts.

Finally, let us drop the assumption that the level of per capita income remains constant and assume instead that it is gradually rising. It seems reasonable to suppose that any growth in per capita income would cause k to increase also.[8] If each person in the population enjoys a higher standard of living, it is not unreasonable to expect that the capital required to produce this higher standard will be larger also. If the ratio of k to y remains constant, which will be true if the capital-output ratio remains constant, the conclusions reached above are unaffected. In this particular case the ratio of population investment to national income will remain constant as long as population grows at a constant percentage rate even though the level of per capita income is rising. Only if k and y grow at different rates is it impossible to state definitely what will happen to the ratio of population investment to national income. However, unless the size of the ratio k/y is inversely affected by the rate of population growth, it will still be true that the ratio of population investment to national income will decline more slowly (or grow more rapidly)

[6] This assumes a constant percentage growth compounded annually.

[7] The proof is as follows. Assume another rate of growth p'' such that $p' > p''$. It is required to prove that

$$\frac{k \cdot p'}{y + \frac{p'}{2} \cdot y} > \frac{k \cdot p''}{y + \frac{p''}{2} \cdot y}.$$

If we divide both sides by k, multiply through by y and then multiply both sides by the product of the remaining denominators we obtain $p' + \frac{p'p''}{2} > p'' + \frac{p'p''}{2}$, which must be true if $p' > p''$.

[8] It should be noted that I am concerned here only with the effects of rising per capita income on the amount of investment induced by population growth. This growth in per capita income will, of course, induce additional investment if the capital-output ratio is to remain constant.

when population grows at a constant percentage rate than when it grows at a constant absolute rate.

In view of these conclusions why have a number of economists placed so much emphasis on the absolute rate of population growth? For with a constant absolute rate of growth one can expect a steadily declining ratio between population investment and national income. As was suggested above, it seems likely that the economists in question have been thinking too much in terms of a static economy in which it might be reasonable to assume that a constant absolute volume of investment would maintain an acceptable level of employment for an indefinite period of time. Needless to say, we live in a rapidly growing economy and in these circumstances we are likely to need a growing volume of investment. There can be little question then that the percentage rate of growth in population is a much more relevant concept than the absolute rate of growth.

The argument advanced here is essentially similar to that given by a number of economists who have discussed the dynamic growth aspects of capital investment.[9] The principal difference is that these economists have been primarily concerned with the relation between capital investment and the rate of growth in output as a whole whereas my argument has been restricted to the relation between population growth and capital requirements. In both instances the basic assumptions are that the capital-output ratio and the average propensity to save remain constant. Given these assumptions Harrod, Domar and others have shown that a constant proportionate (not absolute) rate of growth in output is required to induce sufficient capital investment to offset the amount of saving that would be forthcoming at a full-employment level of income. The required rate of growth is equal to the average propensity to save multiplied by the reciprocal of the capital-output ratio.[10] I have shown that under similar assumptions a constant proportionate rate of growth in population is necessary if population investment is to remain a constant proportion of national income and total saving.

While I have demonstrated that under certain assumptions a constant percentage rate of population growth will induce a level of investment that will remain a constant proportion of national income, this still leaves unanswered the further question of whether one constant percentage rate of growth is better or worse than another. I should like to suggest that for any country at any point of time there is some optimum rate of population growth.[11] An optimum rate of population growth can be defined as that rate of growth which is most conducive to the maintenance of a high level of employment and a rapid rate of economic progress (where economic progress is defined as increase in output per capita). A more rapid rate of growth than this might

[9] See, in particular, R. F. Harrod, *Towards a Dynamic Economics* (London, 1948); E. D. Domar, "The Problem of Capital Accumulation," *Am. Econ. Rev.* (Dec. 1948), XXXVIII, 777-94; and W. Fellner "The Capital-Output Ratio in Dynamic Economics," *Money, Trade, and Economic Growth* (New York, 1951); and the references given by Fellner on p. 106.

[10] Fellner, *op. cit.*, pp. 111-12.

[11] Higgins has suggested the need for such a concept. See *op. cit.*, p. 106.

slow up the rate of economic progress by reducing the average propensity to save, because of the high consumption rate associated with large families, thus in turn reducing the amount of capital investment.[12] A slower rate of growth might induce less capital investment and thus be less favorable to both the maintenance of a high level of employment and the rate of economic progress.

It seems likely that the optimum rate of population growth would change over a period of time as the ratio between a country's population and its natural resources changed. In effect, this means that the optimum rate of population growth would vary as the position of a country's population changed with reference to its optimum population.[13] It would also vary as the volume of opportunities for investment arising out of growth in per capita output changed. When the population is below an optimum level, a high rate of population growth will mean a rapid approach towards the optimum. This movement of the population towards an optimum will cause an increase in output per capita because of the more favorable ratio of total population to resources. On the other hand, with a lower rate of population growth a larger proportion of total savings will go into forms of capital investment which help to raise the level of output per capita. Under these conditions the minimum acceptable rate of population growth would be the rate which, given the average propensity to save and the opportunities for investment related to growth in output per capita, was just sufficient to maintain full employment. A maximum acceptable rate would be a rate so rapid that any further increase in the rate of population growth would cause a slowing up in the growth of output per capita either because it reduced the community's propensity to save or because the total supply of capital equipment did not keep pace with the growth in population. Within the limits set by this maximum and minimum, a range which could be substantial, it might be difficult to determine an optimum position.

In contrast, when a country's population is beyond its optimum, any increase in the rate of population growth above the minimum rate necessary to induce sufficient investment to maintain full employment will be clearly undesirable for it will result in a less favorable ratio of population to resources and a lower level of per capita output. Thus, where a country's population is beyond the optimum, the optimum rate of population growth will depend primarily on the opportunities for investment related to growth in output per capita. In fact, if growth in output per capita alone would induce sufficient capital investment to maintain full employment, the optimum rate of popula-

[12] This introduces the question of the possible effects of population growth on the propensity to save, a difficult problem and one beyond the scope of this note. It also assumes that the amount of investment is limited by the amount of voluntary saving, that inflation and forced saving are prevented by monetary controls.

[13] The difficulties of defining an optimum population have been carefully discussed by J. R. Hicks. See J. R. Hicks and A. G. Hart, *The Social Framework of the American Economy* (New York, 1945), pp. 240-43. I would suggest that the optimum population be defined with reference to the amount of capital equipment, the opportunities for foreign trade and the state of technical knowledge at a given time and that we recognize that this optimum will change over time with changes in these factors.

tion growth would be zero. As Fellner has shown, given a constant average propensity to save (s) and a constant capital-output ratio (R), the required over-all rate of growth necessary to induce sufficient capital investment to maintain full employment is a constant percentage rate of growth of $\frac{(s)}{R}$.[14] When a country's population has exceeded the optimum, the more of this required rate of growth which can be made up by growth in per capita output the lower will be the optimum rate of population growth. When a country's population is below the optimum, it may be difficult within certain limits to determine the best combination of population growth and growth in output per capita needed to meet this required rate of growth.

In practice the concept of an optimum rate of population growth is difficult to apply. Consider, for example, the changes that have occurred in the percentage rate of population growth in the United States over the period 1790 to 1950. The relevant data are given in Table I.

TABLE I.—PERCENTAGE GROWTH IN POPULATION, BY DECADES, THE UNITED STATES, 1790 TO 1950

Decade	Percentage Growth	Decade	Percentage Growth
1790–1800	34.8	1870–1880	26.0
1800–1810	36.4	1880–1890	25.5
1810–1820	33.1	1890–1900	20.7
1820–1830	34.1	1900–1910	21.4
1830–1840	32.7	1910–1920	15.2
1840–1850	35.9	1920–1930	15.6
1850–1860	35.5	1930–1940	7.2
1860–1870	26.6	1940–1950	14.9

Source: U. S. Bureau of the Census, *Historical Statistics of the United States, 1789–1945* (Washington, 1949) and *Survey of Current Business*, July 1951.

If we exclude the decade 1930 to 1940, rates of growth over the period 1790 to 1950 fall into four groups. From 1790 to 1860 population grew at the rate of about 33 to 36 per cent per decade. A sudden decline in the rate of growth occurred about 1860, and thereafter population grew at a rate of about 26 per cent per decade from 1860 to 1890. A further decline in the rate of growth occurred at this time and population grew at about 21 per cent per decade from 1890 to 1910. Finally, with the exception of the 'thirties, population has grown at the rate of about 15 per cent per decade since 1910. Thus there has been a regular step-like decline in the percentage rate of population growth since 1860.[15] A detailed study would be necessary to determine whether these declines in the rate of population growth were accompanied by corresponding

[14] Fellner, *op. cit.*, pp. 111-12.

[15] These data give little support to Hansen's contention that "the percentage decline in population in the United States was not marked until after World War I." See *op. cit.*, p. 299.

reductions in the optimum rate of growth. However, a few observations appear justified. It seems reasonable to suppose that the optimum rate of population growth would be higher during the earlier part of this period when the ratio of population to land and other resources was extremely low and the total population was well below an optimum. Further, the inflow of foreign capital during the first part of this period would raise the optimum rate of growth for that period. It is also possible that the rate of population growth during part of this period may have exceeded the optimum by a substantial margin.

More recently, the population of the United States has probably approached an optimum and may well have passed it. Accordingly it seems probable that the optimum rate of growth is now substantially lower than it was during the earlier part of the period, say before 1900. Some economists, in particular those of the secular stagnation school, are inclined to believe that the rate of growth in recent decades has been below the rate necessary to maintain a high level of employment. However, the occurrence of two world wars and a great depression makes the period since 1910 difficult to interpret and a more detailed study will be needed to determine whether the optimum rate of growth has declined more or less than the actual rate of growth in recent decades. In fact, the whole problem of the relation of population growth to the demand for capital merits more detailed attention than it has yet received.

In view of the recent emphasis that has been placed on the "amazing population upsurge" in the United States it may be useful to note by way of conclusion that although the absolute growth in the population of the United States during the decade ending in 1950 was the largest on record, the percentage rate of growth for this decade was slightly smaller than that of the decade ending in 1930.

CLARENCE L. BARBER*

* The author is associate professor of political economy at the University of Manitoba.

Consumption and Investment Propensities: Comments

Editor's Note: These three comments on the article by Ta-Chung Liu and Ching-Gwan Chang, published in the September 1950 issue of this *Review*, were originally submitted for publication during the period September 1950-April 1951. Publication has been delayed in part by the necessity for revisions, but mainly because the authors of the original article have been out of the country for considerable periods of time.

In an article in this *Review*,[1] Messrs. Ta-Chung Liu and Ching-Gwan Chang set out to test certain hypotheses concerning the relationship between prewar and postwar aggregate spending propensities in the United States. Their model is most unusual. There is no attempt at deflation: all magnitudes are at "current prices." Consumption, C, is made a function of gross national product, Y, and the consumers' price index, P, rather than disposable income, Y_d. Investment, I, is a function of Y and current corporation profits after taxes, F, and the latter is considered exogenous. A valiant attempt is made to

[1] "Consumption and Investment Propensities," *Am. Econ. Rev.* (Sept. 1950), XL, 565-82.

justify these peculiarities; it is the purpose of this note to raise some important doubts.

I. *Deflation*

Liu's and Chang's defense of the use of current price magnitudes is not convincing. Their first argument, that a function based on "money illusion" better conforms to theory than one which relates real consumption to real income, is ambiguous. What are the "theoretical grounds" on which we should expect the absolute price level to play a part in consumption decisions? The authors do not specify. If narrowly defined, the use of the term "money illusion" would indicate that they are suggesting "irrationality"[2] on the part of consumers. Yet, since the implication that a hypothesis of systematic "irrationality" is subject to *theoretical* proof is patently unacceptable, it is more likely that Liu and Chang are thinking in terms of "rationality" in a dynamic world. Either inelastic price expectations or "Pigou effects" could induce "rational" behavior which would appear (to an observer with a static frame of reference) like money-illusion "irrationality."[3]

By accepting the importance of such dynamic effects, however, the authors undermine the logical foundations of their own function. If current prices and incomes are the sole variables relevant to consumption decisions, then the form of the consumption function cannot be governed by tacit consideration of other variables (expectations, nonequity assets, etc.).[4] If prices and incomes are really the only things that belong on the right-hand side, then it follows that only "irrational" behavior can validate an undeflated function. No empirical evidence is cited in favor of such "irrationality" and I, for one, am loath to give up the assumption of "rationality" for a model based on systematic "irrationality."

The authors' second argument, that the indices available for deflation are of tenuous applicability, though correct in itself, is irrelevant. The technical faults of currently used deflating procedures provide excellent reason for cautious interpretation of so-called "real" figures: they do not validate undeflated figures.

Suffice it to conclude:[5] (1) that most prewar studies suggest that deflated

[2] "Irrational" is a poor word for the intended concept but its analogous place in the vocabulary of price theory and the lack of an obvious substitute perhaps justify its use. Note, however, that it must be very narrowly defined as implying nonmaximizing behavior in terms of a specified frame of reference. None of the usual (and emotive) connotations apply.

[3] See Tobin, "Money Wage Rates and Employment," *The New Economics*, Harris, ed. (New York, 1947), pp. 583 ff.

[4] Unless these variables are linearly related to prices or incomes: a presumption not on its face obvious.

[5] Liu and Chang's third defense, that the inclusion of P as a determinant of C eliminates the spuriousness of a high correlation between Y and C which would otherwise dominate the relationship in that Y and C have prices in common, is a more or less adequate counter to the charge of spurious correlation. The problem is a slippery one though. It is true that replacing two uncorrelated variables x and y by zx and zy will result in a non-zero correlation. It does not necessarily follow that a good correlation between zx and zy is spurious, for the relationship between zx and zy might be the *true*

data provide a better statistical fit than do current values, a fact not met by the Liu-Chang arguments; and (2) that, at any rate, a correct choice must be based exclusively on which alternative provides the better (more invariant) hypothesis.[6]

II. *The Consumption Function*

The function used by Liu and Chang is of the form $C = aY + bP + c$, where a, b, and c are parameters.

The authors indicate awareness of several possible ways of refining their function, but do not consider any of these of substantial importance. As regards lags, they state that despite the improvement in correlation that introduction of an additional independent variable necessarily effects, their experiments with lags resulted in only "superficial" improvements (not to mention the lower significance of the correlation) and that at any rate it is doubtful if any significant lags are inherent in annual data.

These points are well taken; nevertheless, their justification for using undeflated figures would have been more compelling had they used quarterly data and then tried lags. Had implicit expectational elements[7] been thus brought in on the right-hand side, their function would have been more readily reconcilable with the assumption of dynamic "money sophistication."

In the use of Y as a determinant of C one can also quarrel with Liu and Chang. Unlike the use of lags, the use of Y instead of Y_d is not just a simplification. The function, as it stands, does not provide us with a testable hypothesis of behavior.

There are three possible methods of approach to "the" consumption function:

1. The "Baconian" inductive-statistical approach: *i.e.*, running correlations between aggregate magnitudes with no attempt at a theoretical foundation, looking for higher and higher correlation coefficients;

2. Setting up hypotheses as to behavior (invariant with respect to a "class of structures"), then testing against relevant aggregates;

3. Basing hypotheses on the behavior of individuals ("households"), aggregating, then testing both against aggregate and individual (micro-economic) data.

If we want to find a consumption uniformity which is invariant to changes in narrowly economic magnitudes, *i.e.*, which will vary only with changes in

---

one. All that can be said is that a high correlation between zx and zy is not conclusive evidence that it is in fact the true relationship.

[6] If I may defend their practice against their own defenses, I would suggest the following: within limits, the inclusion of a linear price-level term in an undeflated relation does provide a rough approximation to a deflated function (*i.e.*, a Taylor's series first approximation). But where the two periods under consideration differ in P as much as do the postwar and prewar, we must be wary of such approximations.

[7] It could be argued that implicit in the exclusive use of *current* magnitudes is a presumption that the elasticity of expectations is unity; that in fact people expect the parameters relevant to their decisions not to change. If people really thought that they were living in a "stationary state," money illusion really would involve illusion, and what was said concerning systematic irrationality applies.

psychological motivation or the institutional and cultural "framework"[8] (and there is little sense in formulating less "fundamental" relationships), the superiority of the last approach is manifest.[9]

The line of argument followed by Liu and Chang seems to have great affinity for the first approach. There is a good fit between C and Y, hence we have *the* (?) consumption function. Their defense against criticism on this count is based on calculations indicating that disposable income is a good linear function of gross national product and that: "projections from the relation between the two during the prewar decade yield figures for postwar 'disposable income' extremely close to the actual figures" (p. 570).

If the "institutional" relationship between Y_d and Y has not changed as between prewar and postwar, it no doubt follows that an apparent re-establishment of the prewar (derived) relationship between C and Y is good evidence that the behavioristic relationship between C and Y_d is the same as before the war. It is important to note, however, that the usefulness of the Liu-Chang study is severely limited, a fact not sufficiently emphasized by their own article. Their so-called consumption function cannot be used either for prediction or for testing hypotheses of consumer behavior. It is not invariant with respect to changes in the Y *vs.* Y_d relationship, hence variations in tax structure, transfers, corporate savings, etc., will invalidate it.

The only positive justification the authors provide for the use of Y is that it simplifies the system. If Y_d is a linear function of Y, it is difficult to see the nature of the simplification. On the other hand, the advantages of using Y_d are substantial.

III. *The Investment Function*

The stated rationale of the Liu-Chang investment function ($I = dY + eF + i$, where d, e, and i are parameters) is that income is a measure of the "level of economic activities which generate demands for capital goods," while corporate profits after taxes "indicate the magnitude of the incentive for actually making the investment at a given level of demand" (p. 568).

Note that F—corporate profits after taxes—is considered exogenous. This in itself makes prediction on the basis of the function impossible, in that current corporate profits are obviously related to the level of current income. More important (given the authors' limited aims), a high degree of collinearity between Y and F renders the two parameters "e" and "d" virtually meaningless.

It is difficult to find justification for this sort of an investment function. The fact that no lags are intrinsic to annual data does not make the function any more useful: no meaningful hypothesis as to the behavior of the individual investor is being tested.

The dismissal of the "so-called 'acceleration principle'" for lack of any evidence (p. 568), seems somewhat rash. Presumably Liu and Chang were

[8] I am fully cognizant of the difficulties these distinctions involve, but they are not of essence in the present argument.

[9] This was first impressed on the writer by Professor M. F. Millikan in his graduate national income course.

thinking of the unsuccessful search for the stipulated I = f (dY/dt) relationship in time series data. Yet the lack of a discernibly consistent lead-lag relationship only indicates that *without* lags the operation of the principle is not evident. It provides no evidence one way or the other as to any delayed effect dY/dt (or dC/dt) might have on I.

At any rate, any function attempting to describe investment which does not assign a rôle to expectations (directly, or *via* lags, rates of change, etc., indirectly) and which is not grounded on a micro-economic hypothesis is justified only if one accepts the "Baconian approach" to scientific inquiry or if one enjoys running correlations.

IV. *Results and Conclusions*

Comparing the projected values of C, I, and Y with the actual *ex post* values, Liu and Chang conclude that since "the actual consumption data for 1946-1948 came *very nearly* [italics supplied] to the estimated figures," with certain cautions as to relevance outside of the range of observation "properly borne in mind, one may be permitted to say that statistical facts do not contradict the conjecture that *the* [italics supplied] prewar consumption function has more or less been restored or that it is in the process of being restored" (p. 573).

One cannot but be somewhat skeptical as to the authors' views on what constitutes "very nearly." During the years 1930-40 the largest percentage discrepancy between actual and estimated consumption was 1.08% (1938), with an absolute average discrepancy of 0.58%. For the three years 1946-1948 the discrepancies run to 4.95%, 5.88% and 2.68%, respectively, all positive (as opposed to prewar when plus and minus discrepancies almost matched each other, 5 for 6).

The estimated investment figures were completely off the mark. The authors suggest that "the failure of the postwar investment expenditures to come up to the levels estimated from the prewar investment function may perhaps be explained *partially* by the feeling of uncertainty which existed in the minds of the entrepreneurs as regards the possible course of the developments of the American economy" (p. 574). The hypothesis that the depressing effect of "uncertainty" on investment was "greater" during three years of uninterrupted high level prosperity (with a backlog of investment demand due to wartime disinvestment in many lines) than during the most depressed decade in U.S. history seems, at best, novel.

V. *Applications*

Liu and Chang apply their results to find quantitative approximations (1) to the extent of "money illusion" in the U.S. economy, and (2) to the "balanced budget multiplier." Both applications bear discussion.

1. In attempting to determine the existence and extent of "money illusion," Liu and Chang correlate real consumption with real income for the 1930-1940 period. They get a correlation coefficient indicating about as good a fit as that provided by the undeflated function. The latter, however, "gives a slightly

better postwar projection," hence "it appears that 'money illusion' did exist ..." (p. 575).[10]

To "give a quantitative indication of the extent of 'money illusion,'" the authors (i) calculate the price elasticity of demand of real consumption for the year 1948,[11] using (*a*) the undeflated function and (*b*) the "real" function; and (ii) take the difference between the two elasticities expressing the result in percentage terms. They conclude, in fact, that their result (4%) "may be considered as a measure of the extent of 'money illusion'" (p. 575).

Unfortunately, the Liu-Chang procedure has no rational justification. Note what it involves. The *same ex post* consumption figures are used to estimate the parameters of *both* functions. One of these functions seeks to explain the figures on the assumption that they were generated by a public whose consumption decisions were dominated by "money illusion." The other seeks to explain them on the assumption that "money illusion" was not of importance. *One of these functions must be entirely spurious.* If we hypothesize that "money illusion" did in fact exist, then we cannot attribute meaning to a deflated function whose parameters were calculated from data generated (by our hypothesis) by a public under the influence of "money illusion." If "money illusion" really did "produce" the data, then we must conclude that had real consumption been a function of real income (*cet. par.*), the consumption figures would have been different. The same is true if we reverse our hypothesis and base our reasoning on the presumption that the data in hand represent consumption as a function of real income.

The *same* data cannot provide meaningful parameters for *both* functions. But if one of the functions is meaningless, the elasticity calculated from it is also meaningless; if so, it is difficult to attribute any significance to the difference between the two elasticities.

2. Liu and Chang calculate a balanced budget multiplier of 2.7. Its improbability is a consequence of the weakness of the whole model. Note that the calculations imply a marginal propensity to spend out of corporation profits after taxes of only .339. There is a certain ambiguity here, since formally this figure refers to $\partial I/\partial F$, with nothing said about the propensity to pay additional dividends out of the extra profits. Yet for their reasoning to be consistent, Liu and Chang must assume either that 66.1 cents of every extra dollar of profits is not spent or paid out in dividends, or that the dividend receivers' marginal propensity to consume is zero. The authors' modest qualification that the "conclusion obtained by applying the system to the analysis of a concrete problem is . . . necessarily experimental in nature and can serve as no more than an initial reference for further work" does not prevent them from concluding that "the consequences of such a policy" (*i.e.*, simul-

[10] One wonders that they found the small differences (0.5%, 0.77%, 0.93%) between the two sets of projections significant (see p. 575).

Duesenberry, Modigliani, Woytinsky and many others have shown that the postwar consumption-saving-income ratio can be accurately predicted by prewar relations without introducing "money illusion" by taking systematic account of postwar liquid wealth position, etc.

[11] Holding money income constant at the 1948 level.

taneous reduction of G and business taxes) "would be even more disastrous if F were partially an increasing function of Y" (p. 576).

Comment

In an article in the September 1950 issue of this *Review* Messrs. Ta-Chung and Ching-Gwan Chang argue that the price level should be introduced into the consumption and investment equations. In justification of this it is argued that, though this procedure gives "about an equally good" fit for the prewar period it gives a better fit for the three postwar years for which data are available.

This argument, however, is open to the following criticism. Both the consumption equations, the one using and the other ignoring the price term, underestimate the actual data for the postwar years; this is only as it should be, for during this period the data were influenced by a special factor, the pent-up war demand. In order to derive the true relationship, one would have to subtract this factor from the actual data, and since we do not know how large this factor is, we cannot say that the equation coming closer to the actual data (in a linear way only, for there are points of inflexion in neither the data nor the estimating equations for these years) gives a better indication of the true relationship. This consideration is enhanced by the fact that a small difference in the estimation of the pent-up demand would destroy the significance of the price term, for the differences between the equation using the price term and the equation ignoring it are 1/10, 1/8 and 1/3 (for 1946, 1947 and 1948 respectively) of the pent-up demand as measured by the difference between the actual data and the better fitting of the two equations. Thus the only evidence to show that the equation using the price term is superior is that of 1948, when the pent-up demand must have been of less importance than in the two preceding years. To argue from the evidence of one year is obviously most tenuous. A similar consideration throws grave doubt upon the estimated value of the price parameter, the calculated value of the price elasticity and also on the introduction of a price term in the investment equation.

THOMAS MAYER*

Comment

The new conclusions with respect to consumption presented by Drs. Liu and Chang in their recent article are as follows:

1. "Contrary to a complete absence assumed in the existing estimates of the (prewar) consumption function, the influences of 'money illusion' are statistically discernible—" (pp. 565, 566).

2. "While it cannot be definitely proven that the prewar consumption function has really been restored during the postwar years, the postwar consumption expenditures do appear to be very close to what the prewar consumption function would require them to be" (p. 566).

It is the purpose of this comment to suggest that in both cases the evidence presented points to the opposite conclusion.

As evidence of the "money illusion" (*i.e.,* that if consumers' real income remained constant but dollar income and prices fell, real consumer expenditure would increase, presumably because prices seemed lower) the authors present two equations for the consumption function. One is a standard function in which income (represented by GNP) and consumer expenditure are deflated for price. In the second, money values of income and expenditure are used directly in the equation and price is treated as an independent variable. Because "The two equations give about equally good fit for the prewar period" (both gave a correlation coefficient of 0.99), and because the new equation "gives a slightly better postwar projection," they conclude that the "money illusion" did exist (p. 575).

Examination of their new equation shows their "money illusion" to be of an unexpected character. The equation is as follows with the usual notations except that Y represents GNP, not disposable income,

$$C = 0.535\,Y + .214\,P - 3.06.$$

This can be converted to real terms by dividing through by P with $C/P = c$ and $Y/P = y$ to give the following equation,

$$c = 0.535y + .214 - 3.06/P.$$

According to this equation a lower price level produces a *decrease* in real consumer expenditure not an increase. This is the "money illusion" in reverse. It is an "illusion" which would, according to the equation, lead consumers to stop spending entirely if the price level were sufficiently low.

This apparent negative "money illusion" would be interesting if the coefficient of price in the formula had significance. Actually the influence of the price factor in the equation is small. At 1940 prices and incomes, a *doubling* of prices would, according to the formula, increase real consumer expenditure by only 2 per cent. Yet the extreme difference in prices for the data used to derive the coefficients was only from 92 to 119. Furthermore, there was a very high intercorrelation between money income (however defined) and the price index in the base period used. *Real* income fluctuated very much as did the consumer price index. Multiplying real income by the price index adds to the intercorrelation. It must be obvious that the coefficient obtained for price in the equation has no significance.

Since the introduction of price as an independent factor does not improve the coefficient of correlation, does not produce the expected relation and does not give price a significant coefficient, it is difficult to see what evidence it provides of the existence of the "money illusion." Rather, the evidence suggests that the simpler formula is the more valid of the two and that, in so far as the new formula throws any light on the "money illusion" it points to its absence.

The question whether the postwar consumption expenditures are in fact "very close to what the prewar consumption function would require them to be" involves two problems: (1) what are the relevant figures, and (2) what constitutes being "very close"?

The authors base their conclusion of the closeness of the postwar expenditure to the prewar function on the more complex of the two formulae. If the simpler and more valid formula is used, the discrepancy appears significantly greater as is shown in the first part of the table below.

Excess of Actual Consumer Expenditures Over Estimated Expenditures

(in billions of dollars)

	By Complex Formula[a]	By Simple Formula[b]
1946	7.3	6.9
1947	9.8	12.0
1948	4.8	7.2
1949		10.2
1950 First half year[c]		8.4

[a] $C=0.535Y+0.214P-3.06$
[b] $C=0.539Y+0.181P$
[c] Seasonally adjusted

The greater discrepancy is particularly important for 1948 since the authors, while recognizing that the actual figures are *consistently higher* than the estimate, attribute this to the pent-up demand arising from war shortages which could be expected to taper off as these demands are liquidated. The revised estimates for the years 1946 to 1948 do not show any such tapering. The lack of tapering is also indicated by the estimates for 1949 and the first half of 1950 which are included in the table. Rather, consumer expenditure appears to have been running some $7 or $8 billion over the prewar relation to disposable income. Since the war, consumers have been spending roughly 5 per cent more than would have been expected on the basis of prewar behavior.

Whether consumption expenditures running 5 per cent above what could be expected on the prewar basis is "very close" to the prewar depends somewhat on the point of view. A 5 per cent rise in the consumption function, if it has occurred, would seem to the present writer a noteworthy shift in a function which has so often been assumed to be stable.

But whether this shift, considered only from the point of view of consump-

tion, is significant, there can be little question that its implications for saving and the saving-investment problem are great. Below are given the actual and estimated consumer savings since the war, arrived at by deducting actual and estimated consumer expenditure from actual disposable income. The figures in parenthesis for 1950 represent actual and estimated savings, excluding the veterans' insurance payments from both disposable income and savings.

	Actual Saving (in billion dollars)	Estimated Saving (in billion dollars)	Ratio of Actual to Estimated Saving
1946	10.3	17.2	60%
1947	5.1	17.1	30%
1948	12.0	19.2	62%
1949	8.6	18.8	46%
1950[a]	12.8 (7.8)	21.2 (16.2)	60% (48%)
Average	9.7	18.7	54%

[a] First half year—annual basis, seasonally adjusted.

Since the end of the war savings have been little more than half what could have been expected on the basis of prewar relationships. Certainly from the point of view of the problem of oversaving it does not seem reasonable to say that "the actual consumption data for 1946-48 come very nearly to the estimated figures" (p. 573).

If an upward shift of something like 5 per cent has taken place in the propensity to consume, it would have considerable theoretical importance. It would tend to confirm the position of those who, at the close of the war, predicted that the great increase in the money supply and the great increase in the liquidity of individuals would give a more or less permanent lift to the propensity to consume.

GARDINER C. MEANS*

* The author is consultant, Committee for Economic Development.

Rejoinder*

Dr. Means' criticisms center around the meaning and the significance of the "money illusion" implied in our equation (1), $C = 0.535\,Y + 0.214\,P - 3.06$,[1] which when divided through by P becomes: $c = 0.535\,y + 0.214 - 3.06/P$, c and y being deflated magnitudes.

* The authors take this opportunity to correct the following typographical errors in the original article (this *Review*, September 1950, pp. 565-82): (1) In footnote 7 (p. 572), the letters C, Y, P, I and F in the symbols RC·YP and RI·YF should appear as subscripts. (2) On page 575 an equation sign is missing before the expression in the thirteenth line from bottom.

[1] Page 572 of the original article. All variables in capital letters are measured in current money values.

Means defined "money illusion" as the situation where "if consumers' real income remained constant but dollar income and prices fell, real consumer expenditure would increase, presumably because prices seemed lower." Since, with y constant, c as calculated from the second equation given above will become smaller if P is smaller, the "money illusion" implied in the above equation would yield "money illusion in reverse" on Means' definition.[2]

There is, however, no standard way of defining "money illusion." Means' definition may be called the "money *price* illusion." Let us define "money *income* illusion" as the situation where, with real income constant but money income and prices falling proportionately, people are led by the smaller money income to believe that they are "poorer" and hence consume less. Our equation yields "money income illusion" but "money price illusion in reverse"; whereas any equation which gives "money price illusion" would yield "money income illusion in reverse." There is little doubt that people know what their incomes and prices are in money terms better than in real terms;[3] hence both types of illusion could exist.

No claim was made in the original paper that the "amount" of "money illusion" implied in equation (1) is large; at the same time, no test of its statistical significance was made. Whether "money illusion" existed significantly in the statistical sense depends entirely upon whether the constant term in equation (1), *i.e.*, -3.06, is significantly different from zero. The standard error of that constant is 1.66 which, for eight degrees of freedom, means roughly one chance in twelve that a constant term as large as 3.06 (in absolute value) or larger would be obtained in the absence of a "money illusion." This is not clearly statistically significant, but the probability is small enough to be suggestive.

Whether on the basis of our equation (1) or (4), the estimated consumption figures were lower than the actual values in postwar years. It must for the time being remain a matter of personal opinion how much of these "excesses" of actual over estimated values represented a more or less "permanent" upward shift of the consumption function on account of the great increase in the liquidity of the individuals, as Means seems to believe, and how much was due to the liquidation of "pent-up demands." The absence of a continuous "tapering off" tendency in the "excesses" obtained from equation (1) would tend to cast doubt, as pointed out by both Means and Mayer, on the interpretation of these "excesses" as reflecting the liquidation of "pent-up demands"; even though it is difficult to believe, on *a priori* grounds, that the fulfillment of such demands did not play a rôle in postwar consumption. In any case, the lack of any discussion of the liquidity factor was undoubtedly a serious error of omission in the original paper.

The essence of Mr. Mayer's criticism is that, since we do not know the

[2] The "absurd" result obtainable from equation (1) mentioned by Means (*i.e.*, consumers would "stop spending entirely if the price level were sufficiently low") is interesting but unimportant; as all statistical functions, when carried far beyond their relevant ranges, are likely to yield economically absurd results.

[3] This was one of the reasons why the consumption function in the original paper was set up in money values, instead of in real terms.

actual size of "pent-up demands," we can not say that the equation coming closer to the actual data (*i.e.*, equation 1) is a better indication of the consumption function than equation 4 when the influences of the "pent-up demands" are removed from the relationship. An assumption implicit in the original paper is of course that the liquidation of "pent-up demands" was somewhat smaller than the total postwar "excesses" in consumption, a hypothesis admittedly impossible to establish by any statistical effort at the present time.

In the discussion of the consumption function in Sections I and II in Mr. Bator's comments, he suggests that there are three possible grounds on which the absolute price level might be introduced into the consumption function: inelastic price expectations, the "Pigou effects" and "irrationality" on the part of the consumers. Since he believes that "the implication that a hypothesis of systematic 'irrationality' is subject to theoretical proof[4] is patently unacceptable," he attributes the introduction of the price level into our equation (1) to the first two factors and then proceeds to criticise the equation on this basis. The "money illusion" implied in equation (1), however, is of the "irrational" type.[5] The criticism, therefore, is not relevant.

Bator believes that "no meaningful hypothesis as to the behavior of the individual investor is being tested" in connection with our investment function, equation 2, which has gross product and profits after taxes as independent variables. If profit incentive as an explanatory variable for investment "is not grounded on a micro-economic hypothesis," one is at a loss to find another that is.[6] A serious omission occurred in the original paper in not having pointed out profits as a major source of supply of capital for investment[7] which would further reinforce the desirability of introducing profits as an independent variable in the function. The authors may perhaps be excused for their "dismissal" of the "so-called 'acceleration principle,'" as any *statistical* attempt to find the "acceleration principle" in a rigid, quantitative form, not necessarily linear and for whatever time-unit (annual, quarterly, etc.), is a dead animal unworthy of revival. On the other hand, the level of output must have influences on the demand for investment as a result of a host of reasons,[8] of which the "acceleration principle" is but one underlying consideration. It is of course extremely difficult to determine on *a priori* grounds the net result of

[4] Equation (1) represents of course an *empirical* attempt to see whether "money illusion" existed.

[5] The "money income illusion" is of the "irrational" type, as a proportional fall in both income and price will leave real income unchanged but will increase the real value of money holdings.

[6] Bator also criticizes our investment function on the ground that we failed to "assign a role to expectations (directly, or *via* lags, rates of change, etc., indirectly)." One has yet to invent a method by which expectations can be included in a statistical function *directly*. Indirectly speaking, it is not necessarily true that expectations must be associated with lags or rates of change. Expectations can be formed on the basis of current values alone.

[7] See the discussion of this point in S. C. Tsiang, "Accelerator, Theory of the Firm and the Business Cycle," *Quart. Jour. Econ.* (Aug. 1951).

[8] Tsiang, *ibid.*. especially pp. 327-31.

these influences on investment, especially aggregate investment. Under such circumstances, it is almost inevitable that one would choose the gross product as an independent variable in the function in order to reflect the influences of the level of output on investment.[9] In any case it does not seem justified to say that a relationship between investment on the one hand and the gross product and profits on the other is in the nature of what Bator called "the Baconian" inductive-statistical approach: *i.e.*, "running correlations between aggregate magnitudes with no attempt at a theoretical foundation, looking for higher and higher correlation coefficients."[10] The relatively large standard error of the profit term merely shows that the influence of profits on investment cannot be clearly segregated by statistical devices from those of the gross product; however, it does not prove the theoretical irrelevance of either the gross product or profits as an explanatory variable for investment.

Space does not permit detailed discussion of the many other interesting points raised in Bator's comment; however, the reply to some of them is already implied in the above discussion. The rest are essentially of the following kinds: a recapitulation of those desirable undertakings which we said we were not in a position to do[11] and a summary of the limitations explicitly enumerated in the original paper.[12] Since these re-enumerations help to emphasize the professed narrow scope and the highly tentative nature of the paper, they are entirely welcome.

TA-CHUNG LIU and CHING-GWAN CHANG*

[9] Even in purely theoretical analysis without any attempt at statistical verification, the absolute level of income (or that of consumption) is included as an independent variable in the investment function. For outstanding examples, see O. Lange, "The Optimum Propensity to Consume and the Rate of Interest," *Economica,* February 1938, and J. R. Hicks, "Mr. Keynes and the Classics: a Suggested Interpretation," *Econometrica,* April 1937. It is of interest to observe that A. Smithies introduced income as an independent variable in his investment function even after the rate of change of income had been included. See his "Period Analysis and Equilibrium Analysis," *Econometrica,* January 1947.

[10] Bacon himself would have objected to such a use of his name.

[11] For example, our failure to use quarterly data on account of the difficulty of applying the existing statistical technique to them, and the absence of explanation for the variation in profits. In so far as the use of the gross product instead of disposable income in the consumption function is concerned, it is a fact that the postwar relationship between these two variables was almost exactly the same as the prewar one. One merely has to substitute this relationship into the consumption function to obtain the relation between consumption and disposable income. (It should be noted that prediction is admittedly not a purpose of the original paper.) Bator also questioned the advantage of using the gross product from the computation point of view. The computation of the model given in the appendix is greatly simplified by the use of the gross product, because the introduction of disposable income would give rise to a problem of "identification" which can be solved only by the laborious process involved in the solution of a certain characteristic equation. It further simplified the computation of the consumption function in the text because the variance and covariance matrix of Y and C had already been computed in connection with the model in the appendix which was worked out first.

[12] Such as those given in connection with the application of the system.

Price Leadership—A Reply to Mr. Oxenfeldt

In a recent issue of this *Review* Professor Oxenfeldt challenged the correctness of some conclusions I reached in an earlier article on the nature and significance of price leadership.[1] In his discussion he raised several questions that are highly relevant to the problem of framing public policy toward price leadership as an industrial practice and pointed out some of the limitations to my conclusions. His comment therefore serves as another reminder (one also appears in my own article at page 900) to the reader that we need a larger number of case studies before the stochastic laws governing the relationships among rivals in oligopolistic industries can be accurately determined.

My investigation (based upon all the published industry studies I could find) led to the following conclusions (paraphrased): (1) Dominant firm price leadership is essentially a problem in monopoly rather than oligopolistic rationalization. (2) The more common variety of barometric firm price leadership, in the absence of supporting arrangements such as zone pricing and basing point arrangements, etc., does not appear to depart seriously from competitive pricing. And (3) extreme forms of barometric price leadership, which might also be viewed as price leadership in lieu of an overt agreement, can effectively circumvent competitive forces only when five specific conditions are fulfilled. These three conclusions led in turn to a proposal that public policy be directed against the more tangible supports to price leadership rather than against price leadership as such.

With regard to extreme barometric price leadership Oxenfeldt asserts that only one of my five specific conditions is essential—the existence of oligopoly (p. 382). He argues that restricted entry, reasonably similar costs among firms, and a market demand curve not greatly exceeding unity, three of my five prerequisites, are not necessary. A fourth—that each producer must view his output as an extremely close substitute for outputs of his rivals—Oxenfeldt accepts in substance but feels that my examples "suggest that [I] exaggerate the need for product similarity" (p. 382). Since on this point we are in substantial agreement, I shall limit my discussion to the remaining three.

He rejects restrictions to entry as a prerequisite on the grounds that new entrants only "limit the gains to firms that are party to such an arrangement" and *might* have no effect on prices (p. 382) (italics supplied). It is true that my discussion did not provide for this contingency, but I am not convinced that it provides adequate grounds for playing down the importance of entry restrictions.

He rejects reasonably similar cost conditions because it "seems unnecessary analytically and also inconsistant with one of the most notorious cases [the United States Steel Corporation] of price leadership" (p. 383). Why it is

[1] A. R. Oxenfeldt, "Professor Markham on Price Leadership: Some Unanswered Questions," *Am. Econ. Rev.*, June 1952, XLII, 380-84. His comment was prompted by my article, "The Nature and Significance of Price Leadership," *ibid.*, Dec. 1951, XLI, 891-905. Except where reference to my own article is obvious, all page citations are to Oxenfeldt's comment.

unnecessary analytically is not explained. Also, before the steel industry can be used as factual grounds for dismissing reasonably similar costs as a prerequisite, it must first be demonstrated (1) that U. S. Steel, over the period its price leadership was effective, was a high cost producer; (2) that effective price leadership did not stem from U. S. Steel's dominant firm position (thereby appropriately assigning steel to the barometric firm discussion); and (3) that effective price leadership was not dependent upon any supporting price arrangements among steel producers. This I submit is a formidable task in view of the historical size of U. S. Steel and a half-century of basing point pricing.[2]

Similarly, Oxenfeldt argues that an elasticity of market demand not greatly above unity seems an unnecessary prerequisite for effective price leadership. He correctly states that the main point of my argument is that near-substitutes set an upper limit beyond which the price leader cannot carry price. I agree with him that effective price leadership could still raise price to the point where near-substitutes prevented further price increases. I also concede that without price leadership prices might be lower—whether *far* lower (as he suggests) or not, would depend on the "closeness" of the substitutes, and in turn, among other things, on the elasticity of market demand.

The difference between Oxenfeldt's position and my own on the matter of prerequisites, however, is principally a matter of degree, and not wholly beyond reconciliation. He himself concedes that four of the market features I list as prerequisites might appropriately be considered "factors conducive to price leadership" (p. 382). I do believe it necessary, however, to correct what appears to me to be a rather arbitrary construction he places upon two of my conclusions. According to him, I concluded that "barometric price leadership gives the same results as competition" (p. 384). What I in fact said was as follows: "Except for the type of price leadership discussed below [price leadership in lieu of an overt agreement] the evidence suggests that the power of the price leader to preserve price discipline derives less from his ostensible status as the barometric firm than from the more overt arrangements which support it. Where such supporting arrangements are not found, the barometric firm seems to do little more than respond to forces of competition" (p. 901).

Also, according to Oxenfeldt, I concluded that ". . . if perchance a dominant firm is an effective price leader, one need only wait a little while and new

[2] We may concede that U. S. Steel was a high cost producer over the time period in question without appreciably lessening the task. However, the testimony before the Cellar Committee, to which Oxenfeldt refers, shows less conclusively that U. S. Steel was a higher cost producer than its rivals than that U. S. Steel was not as efficient as it might have been. The testimony, based on the 200-volume Ford, Bacon, and Davis Report (not yet made public), shows that U. S. Steel's cost accounting system was highly inadequate, its plants (and some of its management) obsolete, and that U. S. Steel had lost ground to its rivals by failing to adapt its production to the newer steel using industries. A more recent treatment of the steel industry, however, shows that before World War II, the Tennessee Coal, Iron and Railroad Company, a subsidiary of U. S. Steel, was probably the lowest cost steel producer in the United States. See a forthcoming study by George W. Stocking, *Basing Point Pricing and the South.*

firms will emerge to end its dominance" (p. 384). What I in fact said was, "Price leadership in a dominant firm market is not simply a *modus operandi* designed to circumvent price competition among rival sellers but is instead an inevitable consequence of the industry's structure. Hence, the only obviously effective remedy for such monopoly pricing is to . . . dissolve, if economically and politically feasible, the dominant firm" (p. 895). I then cautioned that public policy should hardly be directed toward this end before the foundations of the dominant firm's existence had been thoroughly examined, pointing out that entry of new firms had frequently reduced the monopoly power of initial dominant firms as effectively as public policy measures could have been expected to do so. I then cited four industries in which this had been the case, and two in which it had not.

BOOK REVIEWS

Economic Theory; General Economics

Wirtschaftlichkeitsrechnung. By ERICH SCHNEIDER. (Bern: A. Francke. Tübingen: J. C. B. Mohr (Paul Siebeck). 1951. Pp. viii, 156. DM 10.80.)

This book is essentially a German version of the author's *Investering og Rente* (Investment and Interest), published in Danish in 1944, and is one of the series of "Hand- und Lehrbücher aus dem Gebiet der Sozialwissenschaften," edited by Edgar Salin and Arthur Spiethoff.

Dr. Schneider first defines the "internal rate of interest," which is Keynes' efficiency of capital, and the "capital value" of an investment, which is Irving Fisher's "present value."[1] He then describes alternative methods by which the investor, once he has estimated the outlays and receipts attached to an investment and determined a "calculation rate of interest," can compute its profitability, and compare it with other opportunities. The methods, each of which gives the same result, so that choice is a matter of convenience, are: (1) the discount method, by which capital values are determined; (2) the internal rate of interest, or "difference" method, which involves comparison of the internal rate of interest of the differences in the outlays and receipts series of alternative investments with the calculation rate; and (3) the "annuity method," wherein the series are reduced to uniform averages. If an infinite number of investments, which vary continuously according to "one or more variable magnitudes" is available, the investor maximizes capital value by equating the marginal internal rate of interest with the calculation rate. This is possible if within the range of choice the internal rate is falling (p. 51).

Schneider thus explains, with formulae and practical examples, the application of the "'modern theory of investment" to problems of investment choice, replacement dates,[2] evaluation of existing equipment, and optimum sizes of installations and inventory purchases. This explanation is developed most carefully and with admirable clarity.

In his final chapter and in scattered sections in the earlier chapters, the author discusses in rather summary fashion problems relating to the determination of the values which enter into the calculation, and the relative significance of economic calculation among the several determinants of entrepreneurial decisions.

The calculation rate of interest is "in all cases a subjectively determined magnitude" (p. 67). If an investment is self-financed, the rate will "in general" be that rate "which is viewed as normal" in the particular industry (*ibid.*). But if borrowed capital is used, the rate will "obviously . . . be greater than the rate of interest which the investor pays . . ." (p. 66). The magnitude of the difference depends, according to the author, on what *internal* rate the

[1] *The Theory of Interest* (New York, 1930), p. 152.

[2] Much of the material relating to this problem was published in the *Weltwirtschaftliches Archiv* (1942), LV, 90 ff.

investor "wishes to realize" and the risk involved in the investment (pp. 66-67). This is confusing. The internal rate is the rate of discount which equates anticipated receipts with anticipated outlays, that is, what the investor expects or hopes, not what he might wish to achieve. The calculation rate, on the other hand, is a magnitude which the investor views as "suitable" (*angemessen*) (p. 22); but the author expressly warns (p. 128, footnote 1) against the "understandable" tendency of investors to use "too high" a calculation rate as a "safety valve."

Considerations of financing an investment can influence calculations only through their effects on the size of the calculation rate and—though they may force abandonment of an investment—are to be sharply separated from the calculation itself. Comparison, however, of options on the basis of calculations is valid, the author warns, only if choice of a more costly investment does not force the investor to forgo a profitable third investment.

Additional influences affecting investment decisions are the "imponderables" and uncertainty. Allowance for uncertainty by overly conservative estimates, Schneider says (in the cited footnote), "consciously" falsifies the results of calculations. Alternative investments must therefore be weighed, after calculations, in the light of their varying degrees of uncertainty. With respect to a single investment, differing degrees of uncertainty attached to different factors require calculations on the basis of "various thinkable assumptions" (p. 127). The investor, I think, might here be better advised to use Schneider's interesting concept (pp. 62-66) of the "critical value" of a factor, that is, the value at which, *ceteris paribus,* the capital values (profitabilities) of alternatives are equal. Having determined the critical value, the investor could consider whether the probable value would be greater or smaller than the critical value.

The author is a doughty champion of the methods he so ably develops. The imponderables, he admits, "in most cases . . . are the really decisive factors" (p. 129). Nonetheless "nothing would be more mistaken" than to conclude that "the actual calculation plays only a subordinate rôle . . . without calculation a rational decision is an impossibility" (p. 132).

The book is thus both an appeal for economic calculation and a valuable manual for its use. Though intended apparently primarily for practical use, the author's skillful "coördination" of the quantitative criteria of individual entrepreneurial decisions with "modern theory" is of definite theoretical interest.

For American use, one correction may be required. Schneider points out (pp. 95-96) the complete irrelevance of remaining book value in the determination of optimum replacement dates. This may be correct for Germany and Denmark. But in the United States the (present) capital value of the reduction in profit tax is greater if the remaining book value is used at once as a loss than if it is amortized in later years. Thus the fact of unamortized book value shifts Schneider's optimum replacement dates (pp. 81 ff.) forward.

Economie in Zestien Bladzijden of Inleiding tot de Analytische Economie. By I. J. GOUDRIAAN. (Amsterdam: De Bussy. 1952. Pp. xxi, 249.)

Professor Goudriaan is an economist from the Netherlands, where he occupied various leading positions in industry and taught at the Institute of Technology in Delft. Recently he emigrated to South Africa and is now at the University of Pretoria. This book is intended to prove an earlier statement of his contending that "all really exact scientific truth in economics could be summarized in a little book of perhaps twelve or sixteen pages." At first sight there is a considerable discrepancy between the title of this volume *(Economics in Sixteen Pages)* and its actual size, but the title is justified by a first part which does outline the author's views in sixteen pages of small type, the remainder consisting of comments and elaborations.

The choice of subjects, and indeed the whole project, is indicative of a highly personal opinion as to the contents of economics. There are few references to economic theory in the narrow sense; modern price theory with its many ramifications is completely ignored. This is a consequence of the author's opposition to determinism and his emphasis on what he calls "indeterminate quantities," such as supply and demand on a market where speculation is dominant. He believes that economic analysis, if it is to have practical relevance, should be based on the following three axioms:

1. An action of one person, who is not bound by tradition or external compulsion, is indeterminate.

2. The aggregate of the actions of a number of persons who react independently is a stochastic variable which approaches determinateness as their number increases.

3. The aggregate of the actions of a number of persons each of whom is to an important extent conscious of the actions of many of the others is indeterminate, no matter how big that number is.

What is left of economics under these restrictions is a system of macroeconomic equations which are made meaningful by a division into sectors and various other assumptions which are claimed to be valid empirically. At this stage readers may well feel that they have to take a great deal on trust and that the author's assertions might with advantage have been supported by more detailed econometric investigations. However this may be, the model presented is of considerable interest and fits to some extent in the recent work in economic dynamics by Hicks, Harrod, Goodwin and others. Three sectors are distinguished, corresponding roughly to raw materials (quantity determinate, price indeterminate), heavy industry (both price and quantity indeterminate), branded and retail goods and services (both price and quantity determinate). The model contains a multiplier, an accelerator and autonomous investment, but the definitions are sometimes rather unusual. Much attention is paid to capacity limits as a source of instability. In accordance with the author's methodological views the model is not complete; its parameters are subject to shifts and there is no necessary sequence of upturn and downturn.

In a system of this kind there is evidently great scope for government

intervention to increase stability by making the indeterminate quantities more determinate. As regards the prices of raw materials, Goudriaan's solution is a commodity currency, as advocated in the United States by Benjamin Graham. Goudriaan's advocacy of this scheme preceded Graham's book by several years, however; one may indeed surmise that the present work was developed originally as a rationalization of his views on monetary policy, which is not of course a reflection on its merits. There is an interesting discussion of the composition and operation of a commodity reserve.

In order to stabilize the heavy industry sector the author proposes a system of deferred investment projects, calculated at a discount compared to the price for immediate execution. There would be a pool of such projects for each branch of industry and those who accept a contract would have to start work at the option of the principal. The difficulties in such a scheme are obvious and unfortunately the author's exposition is too brief to be convincing.

Economics in Sixteen Pages abounds in brilliant suggestions and persuasive arguments, and many of its ideas deserve to reach a wider audience than that to which it is now available. Its methodological claims are perhaps too much at variance with recent developments to be taken altogether seriously, especially as the author does not seem to be familiar with the present state of our science outside his chosen field of macro-economics. Neither this nor the somewhat bellicose tone in which the book is written should deter us from appreciating its real contribution to our knowledge of the economy.

Het Systeem van de Marktvormen (The System of Market Types). By F. J. DE JONG. (Leiden: H. E. Stenfert Kroese.N. V. 1951. Pp. x, 214. *f* 14.00.)

According to Professor de Jong, the development of price theory is currently hampered by the absence of a clearly defined and universally accepted system of market models or types. He states that this obstacle was nonexistent prior to about 1930 because for the most part price theory was formulated under the assumption of "homeopolyopolie/homeopolyopsonie (plus free entry plus a nonregulated market)."

This convenient though primitive state of affairs was rudely disturbed in the early 'thirties when, building on the foundations provided by Sraffa, Mrs. Robinson, Chamberlin, and von Stackelberg made their well-known contributions. De Jong notes that neither Chamberlin nor Mrs. Robinson formulated a clear-cut system of market types. Von Stackelberg did, but used only one criterion—the number of participants in the market.

Unfortunate as this was, from de Jong's viewpoint, these three authors made matters worse (though certainly not deliberately) by each devising a nomenclature for market types that is in some respects different from that of the other two. De Jong characterizes the resulting terminological chaos as similar to the language difficulties that plagued the tower of Babel.

Praising Triffin's attempt to provide a standard terminology, de Jong proceeds to examine it critically and then proposes a system or, more precisely, a matrix of market types that he hopes will win universal acceptance.

Het Systeem van de Marktvormen begins with a description of pre-Triffin struggles to define clearly market types other than homeopolyópolie/homeopolyopsonie. This survey of the literature—a not unusual part of many continental European books in economics, no matter what the particular subject—assures the reader that the author has studied his antecedents. However, in this instance it is not merely a display of academic erudition. It provides a background that clearly illustrates some of the difficulties encountered by those who have grappled with the problem of classifying market types. Further, it enables de Jong to dispose of certain definitional matters and to set the stage for his analysis of the criteria to be employed in distinguishing various types of markets.

The first criterion "the eventual homogeneity of market and commodity," —is based upon the absolute value of the cross elasticity of demand for the product of a seller, assuming a fall in his price relative to that of his competitors. If this cross elasticity is very large (approaching infinity) for every seller vis-à-vis his competitors, homeopoly exists. If this elasticity is 0, heremopoly (isolated product) prevails. And if the cross elasticity is greater than 0 but less than infinity, heteropoly characterizes the market.

The second criterion, "the number of sellers," also utilizes the cross elasticity of demand coefficient but in this case the supply price of the individual seller is assumed to rise relative to that of all other sellers. Assuming homeopoly, for example, the individual seller is a homeoligopolist if the appropriate coefficient of the cross elasticity of demand is greater than 0. This indicates that other sellers will gain an appreciable increase in quantity demanded at their price. If the individual seller is a homeopolypolist, then the coefficient will be very nearly equal to 0, indicating that the other sellers will gain almost nothing in quantity demanded at their price. The second criterion enables de Jong to formulate five types of relationships between sellers. They are monopoly and polypolie, and three kinds of oligopoly—symmetric, asymmetric, and mixed.

By combining the classifications obtained under each of the criteria, nine market types emerge. Since the same types are applicable to both the buyers' and sellers' side of the market, there are eighty-one possible market types.

Next, de Jong compares his system with others, making an especially elaborate comparison with Fellner's. He also shows how simple it is to find equivalents in his matrix for the diverse terminology in use today.

He then goes on to indicate the relation of his market types to reality, concluding that asymmetric and mixed heteroligopoly are characteristic of the markets for industrial products and that agricultural products are sometimes sold in markets very nearly approaching homeopolypolie/homeoliogopsony. In any event, homeopolypolie can more frequently be used as a starting point for an analysis of agricultural markets while in the industrial markets heteroligopoly appears to be generally applicable.

De Jong inquires whether it is necessary to alter his market types if

changes occur in the conditions of entry or if government regulates the markets. He observes that ". . . the kinds of entry and the question of market regulation do not change the market types themselves but do change operations within them." Entry, market regulation, and market type are the three "objective circumstances" (given conditions) under which the exchanges take place in the market.

Viewed in the light of the author's objectives, *Het Systeem van de Marktvormen* is a success. Yet the reviewer was left with a vague feeling of discontent. Perhaps this was attributable to a prejudice against a taxonomic endeavor based upon dissatisfaction with other classificatory systems rather than upon the development of a theory that clearly demonstrates the relevance of the market types constructed.

Still, by providing a standard terminology and a system of precisely defined market types de Jong may well have contributed importantly to the advancement of price theory. Attempts to construct theories under his definitions may be successful. If not, they may lead to a reformulation of market types based upon other criteria. In either event, economics will gain.

University of California, Los Angeles

A Survey of Contemporary Economics. Volume II. Edited by BERNARD F. HALEY. (Homewood, Ill.: Richard D. Irwin, for the American Economic Association. 1952. Pp. ix, 474. $5.00.)

The first volume of *A Survey of Contemporary Economics* has made for itself an indispensable place in every economist's library. The second volume treats fields which were neglected in the first volume and, by adding to the completeness of the coverage, more than doubled the usefulness of the whole undertaking. Economic literature has become so specialized that the expert in one field will welcome a concise and intelligent survey of what has been going on in other fields. The second volume shows at least the same care in the selection of authors and critics and the same high scientific standards of the contributions as the first volume.

The coverage is still not quite complete. The editor mentions in the preface location theory and social security as examples of fields which are not covered. One might also ask why agriculture is treated as a separate field but not such other specific areas of economic activity as mining, manufacturing industry, construction, transportation, services, distribution, etc. I do not suggest that all these fields should have been covered—certainly not within the two volumes—but it might have helped the reader if the preface had given him some rationale of the selection. Perhaps there is room for a third volume.

The second volume again presents a systematic and balanced review of recent literature in the fields that are covered. Beyond that, the authors appraise the accomplishments, point at weak spots and gaps in the research work and identify directions in which further work would be most important. The authors were asked to present a review of and not an original treatise in

the field. The editor states in the preface that the authors, "perhaps with one exception," have exercised the requested self-restraint. He did not name the possible exception and thus the reader is left with the teasing task of guessing which contributor the editor had in mind.

Even though no prize is offered in this quiz, the reviewer is rash enough to volunteer a guess. He would name Baran's article on "National Economic Planning" as the possible exception to which the editor alluded. Baran's is a provocative essay but not a balanced review of the literature in the field. The author cannot do justice to "Planning under Advanced Capitalism" (and that includes full employment and economic stabilization policy) because he believes that the most promising methods of a full employment policy are incompatible with the controlling interests in capitalistic society. This thesis follows from an extremely narrow theory of class interests and the state. Baran seems to reach the conclusion that a government that tackles the problem of instability under capitalistic institutions is bound either to compromise its objectives or to become fascist. Thus, besides fascism, socialism is the only realistic alternative to large-scale unemployment. For empirical proof, Germany is cited as a case in which "big business dominated the policies of the . . . fascist state." Even though the author claims that this is one of the few matters of "general consensus" among the observers, I question both the alleged fact and the logic of the argument. I find it useful for the reader to become acquainted with this very significant inversion of the "road to serfdom" argument but I cannot recognize this essay as a balanced appraisal of the work done in this most crucial area of economics.

The two official critics of Baran's essay, J. K. Galbraith and Adolph Lowe, express their uneasiness about some of these conclusions. What is called for in this case, however, are not a few polite paragraphs combining praise with some disagreement, but a full-length exposition of an open-minded approach to the theoretical and practical work done in the field of employment and stabilization policy.[1]

I have singled out Baran's article because it is one of the most interesting contributions, but, at the same time, the only piece in the volume which fails to give the reader a balanced survey of the contemporary work. In some other cases, gaps in the treatment by the authors are brought to the readers' attention by the critics.

The reviewer is tempted also to single out some of the essays for special praise. Certain articles are outstanding in judicious selection and readable presentation of the work done in complex fields. Emphasizing that this is a subjective judgment, I would like to mention Moses Abramovitz's "Economics of Growth" and Ruth Mack's "Economics of Consumption" as particularly useful contributions.

[1] William Fellner's article on Employment Theory and Arthur Smithies' article on Federal Budgeting and Fiscal Policy in Volume I contribute to the topic but do not focus on stabilization policies.

Yet there is still another thought that is haunting this reviewer. The book is written by economists for economists who want to inform themselves of what is going on in a field in which they have not specialized. This it does in a wholly satisfactory manner. But what if, by some mishap, the book should fall into the hands of a physicist, or a business man, or a trade union official, or just some layman who is concerned about the economic problems of modern society and who wants to learn about the contribution economics is making to their solution? I am afraid these laymen would not gain the impression that economics is making a very constructive contribution to the problems of our time.

Is this a criticism of editor and authors or does the volume correctly reflect an unfortunate state of our science? Could we say that the editors of both volumes have defined economics too narrowly, *i.e.*, as what may be called "academic" economics, and have neglected some relevant developments which have taken place outside "academic" economics? Of course, the academic teacher is supposed to be familiar with the research work done by workers outside as well as inside academic institutions. In addition, of the authors and critics who contributed to the volume, almost one-half are, or were, associated with a research organization (the National Bureau is particularly well represented) or with some government research work. Furthermore, the editor made a very commendable effort to have the writers review the methods actually used in economic research. Richard Ruggles' "Methodological Developments" offers a good appraisal of the value of the mathematical and econometric method and the usefulness of social accounting. Yet only a very few paragraphs are devoted to a review of the way in which these and other methods are actually used by those who are struggling for solutions of the many urgent economic problems. It would have been of interest if Ruggles had given us a survey of the methods through which economics responded to the various problems with which it was confronted in recent times and which it was not adequately equipped to handle.

Government has been faced with new responsibilities for economic stabilization, and it would be of interest to appraise the methods of research used in discharge of their functions by such government agencies as the Council of Economic Advisers and the staff of the Joint Committee on the Economic Report.[2] Economists confronted with testing the feasibility of mobilization plans or with strategic target analysis have had to develop new research methods. Government officials concerned with the development of public enterprises, such as water development projects, have been looking for standards and criteria for the selection and determination of government programs. Large corporations have felt the need to embark on long-range investment planning and have turned to economists for developing appropriate analytical methods. International organizations have been concerned with judging, for instance, the international distribution of the defense burden (North Atlantic

[2] The work of the Council is mentioned incidentally in one footnote of the text. Irrespective of whether or not one agrees with the work of these agencies, I feel that an appraisal of the research methods they have developed belongs in a Survey of Contemporary Economics.

Treaty Organization) and with other problems of resource allocation which have raised very fundamental questions.

Perhaps some of the methods actually used fall under the verdict of Stigler, quoted by Ruggles, that the recent past was a period "of clever gadget and the plausible surmise—the age of the easy answer." Whatever the value of the methods used, they belong to contemporary economics at least as much as the methods used in learned debates.

The development of a science always must be understood in terms of the stimuli operating in two different directions. There is first the "academic" level of science itself. Existing theories are re-examined by each new generation of students; some theories are found defective and improved or supplanted by other theories. That is "orderly" scientific progress. There are, however, also the impulses coming from historical events which cannot be adequately tackled with the analytical tools developed in the past. When the basic assumptions on which former theories were built are no longer valid, new approaches must be developed, so to speak, on the spot. One may debate whether the science of economics has or has not responded well to the great challenge of our time. One may debate whether the methods developed "on the spot" are really new or are adaptations of conventional tools, or are only props used by "fake" economists. In any case, this survey of contemporary economics does not convey to the reader the dramatic fact that economics today is tested on many fronts and that the tools of economic analysis are built or rebuilt as they are used or, possibly in some cases, misused.

Also, under the subject of *Welfare Economics,* there is a great discrepancy between the "academic" discussion and what I may call welfare economics "in action." Boulding's survey of the "academic" discussion is in itself a gem of clear and incisive presentation of a highly abstract and complex topic. His conclusion that welfare economics as a field of economics is bound to founder and must be replaced by a broader approach of social and economic ethics is impregnable. When he comes to discuss the contribution of welfare economics to economic policy he winds up with the understatement that "the record is not too encouraging." Some readers may be reminded of the parable of the medical authorities who, when called upon for help in an epidemic, began their work by debating the question as to how they could decide whether the life of the diseased was worth saving.

In the work of economics, it is often necessary to proceed on the basis of working hypotheses. The economist has constantly to relate his work to some, perhaps only vaguely defined, system of values as it grows out of the society and the time in which he lives. When decisions are to be made on allocation of scarce resources, when standards are developed for health or education, when judgments are made about the degree of freedom and control which appears tolerable—in all these cases, the economist is called upon to provide some basis for the aid of those who have to make the decisions. There is, I am sure, some relationship between this welfare economics in action and the welfare economics in the academic definition of the term. I think that in a Survey of Contemporary Economics it would have been of interest if the more abstract treatment had been related to these working hypotheses of welfare

economics. In this perspective the record might not have appeared quite as discouraging as stated by Boulding.

Both Ruggles and Boulding are certainly aware of the methods and the working hypotheses that must be used by the economists on the firing line but somehow or other the authors of this volume apparently felt that they should stay in the rarefied atmosphere of academic economics and not let the reader come too close to the smell of blood and sweat emanating from the battlefront. But I wish to emphasize again that the volume is extremely successful in reviewing the state of economics as it is usually defined.

GERHARD COLM

Washington, D.C.

Vollbeschäftigung Inflation und Planwirtschaft. By A. AMONN, L. BAUDIN, C. BRESCIANI-TURRONI, H. S. ELLIS, W. EUCKEN, F. A. HAYEK, J. JEWKES, C. IVERSEN, F. A. LUTZ, W. RÖPKE, and J. VINER. (Erlenbach-Zurich: Eugen Rentsch. 1951. Pp. 361. Sw.fr. or DM 15.50.)

The passing of fifteen years since the publication of Keynes' *General Theory* should be enough, especially in our rapidly moving age, to provide the perspective necessary for an objective appraisal of Keynes' influence on economic policy. The desirability of having such an appraisal needs no stressing. Keynes had a profound influence on wartime and postwar economic policies in many countries; and in the course of applying these policies many difficulties were encountered, mistakes committed, and unexpected and undesired consequences brought about. A critical appraisal of this experience, a comparison of it with the experience of countries that employed more orthodox policies, and a modification, in the light of all this, of our principles of economic policy—this is the task undertaken in the book under review.

The eleven authors, whose essays constitute the book, represent seven countries, of which three were and four were not influenced in their postwar economic policies by Keynes' teaching. The group, which contains many distinguished names from both sides of the Atlantic, was in an exceptionally favorable position for an appraisal of Keynes' influence. Indeed, many of the papers give accounts of postwar economic policies and specific aspects of such policies; and most of the papers, considered by themselves, are important, interesting, and well worth reading. But judged as a whole, the book fails, and fails fairly completely, to accomplish what it professedly set out to do.

For this there are a variety of reasons, the most important of which is the principle on which the contributors were selected. Every book must have some unifying principle; and this book has neither the unity of the *Festschrift,* whose authors have a great teacher and his influence in common, nor that of the books made familiar to us by the able editorship of Seymour Harris, in which different authors discuss the same subject in its different aspects or from different points of view. The publisher's announcement that the book deals with Keynes' doctrines is somewhat misleading—a fact which this reviewer first suspected when he saw in the index the names of Lycurgus and Lysenko and found Senator Paul Douglas rubbing shoulders with Diocletian

and (thanks to German spelling) Dschingis Khan. Indeed, three articles (Baudin, Jewkes, and practically all of Eucken) are concerned solely with planning and its evils (hence Genghis Khan); and their only connection with Keynes is that according to some of the contributors full-fledged planning is the inevitable consequence of Keynesian employment policy.

The bond that holds the book together is that all its authors are concerned with some form of economic policy, and that each author is against whichever form of economic policy he is discussing. This is a very loose unifying principle and—to judge by the evidence of this volume—a very unsatisfactory one. To begin with, the negative attitude of all the authors is likely to arouse the reader's suspicion that the book is biased; and this suspicion may well keep from reading it all but those who share its opinions to begin with. Secondly, dealing with several vast subjects, the book inevitably spreads itself thin; and, with the editors' dislike of planning apparently extended even to the coordination of the different contributions, there is much repetition and overlapping, which make the substance of the book even thinner. Statements of opinion abound and are too often repeated, while arguments to substantiate them are few and far between. Thirdly, with contributors chosen for their uniformly negative attitude toward different economic policies, the reader is almost certain to impute to them a negative attitude towards *all* economic policies and an altogether greater uniformity of opinions and attitudes than is, in fact, justified. Readers will gain a false impression of the opinions of some of the authors—an especially unfortunate result, because a subsidiary aim of the book is to acquaint Swiss and German readers with the opinions of foreign economists.[1] Also, a few of the authors betray bias by making extreme or emotionally charged statements; and readers may well impute this bias indiscriminately to all the authors.

Let me quote two of the statements I have in mind. (1) The introduction has this to say about the United Nations report on *National and International Measures for Full Employment:* "We have lived to see Keynesianism driven to its logical extreme in the form of an official document which advocates, in all seriousness, the international application of Hitlerite economic methods for the safeguarding of the free world. It is no exaggeration to regard the U.N. report as the advocacy of an international program for safeguarding freedom by means of unlimited coercion by the state" (p.15). (2) In an article tracing the historical origins and causes of economic planning, Baudin cites as an important cause, "man's excessive pride. The individual is no longer content with his having gained far-reaching mastery over the forces of nature; drunk with power,[2] he believes that he can also overcome the natural laws [of the

[1] To give an example, in this volume Jewkes castigates the pricing policy of Britain's nationalized industries and generally makes clear that he is no friend of economic planning. Yet, he is far from being an anti-Keynesian. In fact, on the basis of the relevant parts of his *Ordeal by Planning,* he might be labelled a Keynesian by some of the other contributors to this volume. Those, however, who make his acquaintance through this volume would never suspect this—as indeed they might never suspect the existence of economists devoted to freedom and yet sympathetic to Keynes and his ideas.

[2] In seinem Machtrausch.

market], which the Physiocrats discovered" (p. 69). The book has important and interesting things to say on both subjects; but statements like these are not likely to enhance the reader's confidence in its objectivity.

The negative attitude of the book accounts for its failure in yet another way. In the chapters dealing with Keynes' influence, Lutz gives a good discussion of the cumbersomeness of fiscal policy in the United States and the consequent difficulty of navigating between the Scylla of unemployment and Charybdis of inflation; Ellis deplores the abandonment of monetary policy in favor of fiscal policy and direct controls; Bresciani-Turroni points to the inadequacy of Keynesian analysis and remedies for dealing with Italy's unemployment problem; Hayek presents the important argument that full employment policies interfere with the proper allocation of labor among different industries, suggesting that Britain's employment policy retarded the adjustment of her economy to the changed requirements of the postwar world; and several contributors (especially Amonn, Hayek, Iversen, Lutz, and Viner) argue, what is perhaps the main theme of the book, that a full employment policy inevitably leads to inflationary pressures and direct controls to contain them, and that these controls in turn inevitably lower efficiency, stifle initiative, and destroy freedom.

These topics are among the main economic problems of our day; and their discussion is well worth while, provided it contributes to their solution. But the majority of the authors take a completely negative attitude. In some of the papers this is natural and called for by limitations of space or the particular way in which the author posed his problem; but in others it is not natural; and it is these others which, with their stronger language, set the tone of the entire book. The main thesis that emerges is that periodic unemployment is inevitable under *laisser faire,* whereas the loss of personal freedom, initiative, and efficiency is inevitable under a full-employment policy; and since unemployment is the lesser evil of the two, we should unlearn the lessons Keynes taught us and abandon all full-employment policies.[3] Faced with these as the only alternatives, most people would probably accept the conclusion; but this book fails to convince the reader that there are no other alternatives. None of the papers explores the middle ground, none of the authors even asks the question whether we could not learn from past mistakes and develop an employment policy that would avoid the evil consequences of inflation, direct controls, and the loss of freedom. It may yet prove true that there is indeed no middle ground between the two extremes; but the book under review seems to jump to this unpleasant conclusion rather than reach it as a result of analysis.

TIBOR SCITOVSKY

Stanford University

[3] It is impossible to tell whether this complete rejection of Keynesian policies implies a rejection also of Keynesian analysis. The only statement on this subject is made by Hayek, who refers to Keynes' employment theory as ". . . a carefully thought out, yet probably erroneous theory . . ." (p. 196).

Application of Linear Programming to the Theory of the Firm—Including an Analysis of Monopolistic Firms by Non-Linear Programming. By ROBERT DORFMAN. Bureau of Business and Economic Research, University of California. (Berkeley and Los Angeles: University of California Press. 1951. Pp ix, 98. $3.50.)

Linear programming, something of a mystery to all except the increasing band of its advocates, now invades one of the central areas of economic theory—the theory of the firm under static conditions—thus hastening the day when those still uninitiated must come to terms with it. The first question they must ask is what linear programming is, what its distinguishing features are. Then they must ask where it is applicable, what it can contribute, and whether it will supplant competitors. Those who would make a start on answering such questions can do no better than to read the first and last (4th) chapters of this little monograph by Robert Dorfman. The heart of the book lies, however, in the second and third chapters which set forth the mathematics of linear programming for the competitive and the monopolistic firm, some of whose factors are fixed in amount. These central chapters were not written for those whose mathematical equipment is too meagre to include facility in matrix algebra, although their brevity will be approved by econometricians. To the present reviewer, whose competence in mathematics falls far short of what is desirable these days, it seems unfortunate that this volume provides only part of a bridge to a nearby peninsula of linear programming, when more pages might have attempted to carry nonmathematicians to the shore of that strange land.

The problem which Dorfman attacks is that of defining an optimum production program for a firm which possesses fixed quantities of certain factors and has open to it various production processes in each of which the proportions of factors are fixed but the scale of which is variable. A firm's optimum program is obtained by combining available processes at appropriate (positive or zero) levels. The mathematics of the solution constitutes the core of the book; it involves maximization of a linear function for competition and of a quadratic function of process levels for monopoly. The assumptions underlying linear programming are discussed briefly in the final chapter, perhaps too briefly at least in the case of linearity (constant returns to scale for each individual process). The problem of uncertainty is not treated but is left to the further development of stochastic models.

The relationships indicated between linear programming and the usual marginal analysis of the firm call for comment. Sometimes the argument stresses the differences between the two approaches and the superiority of linear programming, as, for example, "The type of decision which faces a firm using industrial processes is, therefore, essentially different from the decisions contemplated by the marginal analysis" (p. 11), and, "For the study of decisions in such an industrial milieu, an analytic apparatus is required whose structure parallels the structure of the decisions to be analyzed" (p. 11). Linear programming is said to be designed for situations where the choices are among combinations of discrete processes, affecting the inputs in a group simultaneously, whereas marginal analysis requires differentiability

of product, revenue and cost functions with respect to each input and output independently, and applies only if individual inputs are continuously variable. It should be said, however, that production sometimes admits of groups of processes which are such that within each group processes differ relatively little from each other (approximating continuous substitution within a certain range), and between groups substantial differences obtain.

At times the book seems to stress the similarity of the two approaches. Sometimes the difference between them is a matter of using different language to represent the same situation (p. 18). Despite seemingly rigid technical assumptions, linear programming can approximate any degree of substitutability by the introduction of a large enough number of processes which differ from each other only slightly (pp. 83-84), and in any case provides continuous substitutability between "scarce" factors (up to certain limits) by varying the relative intensities of different processes. The linear programming approach can, then, handle the case of continuously variable proportions, but some persons may feel that it is straining the usefulness of the technique to regard continuous changes in factor proportions as substitution of one fixed-proportion process of production for another.

In the end the author concludes that linear programming and the marginal analysis are theories each of which can be applied to two types of decisions (exemplified by the farmer's choice of crops and his choice of methods of growing them), but that each approach should be used in connection with the decision for whose analysis it is better adapted (pp. 84-85; see also pp. 87-90 for further distinction of the problems to which each is suited). In addition, the claim is made that linear programming is a superior technique because it is practical and deals with concepts more familiar to business and more readily measurable than those of marginal analysis (p. 80). This does not mean, however, that the typical entrepreneur can follow the mathematical procedure outlined any more than he can employ the usual analysis in terms of the calculus. It means that the entrepreneur thinks not in terms of how much of each factor to use, but in terms of the extent to which he will use an available process of production.

An inadequate explanation is given of the rôle of factor prices in the analysis. After pointing out that linear programming is concerned, like conventional theory, with efficient allocation of scarce resources, Dorfman adds, "Unlike conventional theory, however, linear programming appears to arrive at an optimum allocation without recourse to the concept of price" (p. 45). He thereupon discusses the imputation of values to the fixed factors, and shows that the mathematics involved is similar to that involved in the optimization problem already solved. However, this discussion of the imputation problem is not an adequate substitute for a clear explanation of how the prices of fixed and variable factors affect the optimum program. The prices paid for the fixed factors are fixed costs in the short run and are, therefore, (properly) disregarded in the determination of the short-run optimum program, which is the problem with which the book deals. Moreover, the static nature of the analysis makes it necessary to rule out, though the author nowhere makes this

explicit, the possibility that the optimum program might be different if some of the factors whose short-run supply is absolutely limited could be used, perhaps to better advantage, in later production program periods. As for the variable factors, their prices are taken into account in defining the unit level of a process as that which yields a dollar of revenue above the costs of the variable factors used. There is no discussion, however, of the manner in which a change in relative prices of factors would affect the optimum program by affecting the relative net revenues of various processes. The omission may result in a false impression of the rôle of factor prices in the optimization problem. A more complete statement of the economics of the firm in the short run under static conditions would have to deal explicitly with the effect upon the optimum program of different relative prices of variable factors.

The volume merits attention, whether the mathematicians have any quarrel with it or not.

HARLAN M. SMITH

University of Minnesota

The Industrial Economy: Its Technological Basis and Institutional Destiny. By CLARENCE E. AYRES. (Boston: Houghton Mifflin. 1952. Pp. x, 433. $4.00.)

This unusual volume is designed as either text or supplement for an introductory course in economics. It avowedly and actually reflects two distinct approaches. The first is that it is inappropriate to present beginners with merely the alternative explanations of disputed points. Since beginners can hardly be expected to make firm and wise decisions where the experts are uncertain, the text, while recognizing the controversy openly, should take and present an honest stand. If the prospective user of this text likes this basic method, he will be particularly interested in the points of view which Mr. Ayres chooses to espouse, which are taken up later in the review.

Secondly, the book is a self-proclaimed "institutionalist" approach to introductory economics, and bears little resemblance in content, method, or conclusions to traditional texts. For example, in this text history and sociology participate more or less equally with economics in explaining the phenomena usually explained in economic terms, at times almost displacing economic reasoning. The desirability of such an approach depends in large measure on the school curriculum, particularly the extent to which the students take other courses in social sciences.

The plan or organization of the book also represents a conscious and drastic change from the usual method in college-level texts. After several chapters of background material, the volume consists almost entirely of discussions of some economic problems, introducing only such economic concepts and principles as are directly required for those problems. Thus the subjects of banking and the monetary system become subdivisions of a chapter on deficit financing, and taxation appears in the rôle of a tool in planning and economic stabilization. The other problems examined (as shown by chapter headings) are economic instability, its relation to war, social security, public works,

the general welfare, freedom and power, and the destiny of industrial society. This approach results in the deliberate omission of much that is included in the usual text.

The general impression is given that there are two groups of economists. The one consists of Ayres, assisted by Veblen, Keynes, and the Brookings Institution; the other consists of all other economists, from Adam Smith onward. The teachings of the second group constitute the obvious error, to which the truths found by the first group stand in bold contrast. Presentation of various ideas often proceeds by setting up the erroneous teachings, as straw men, and tearing them down. The method is apparently used with awareness that it will annoy most economists, but would seem to this reviewer to be somewhat tiresome to college students as well. It is alleged to have been well received in the classroom, probably due to the success of the author as a teacher.

As to the validity of the reasoning and conclusions of the book, this reviewer feels he can most fairly and accurately convey a sense of the book's merits by some quotations or paraphrases. Care has been exercised to make these reproduce faithfully both the "feel" and the quality of reasoning of the whole. For convenience, the citations carry page references to the original.

1. "Thus even today we continually talk of extending the 'advantages' of education to all our youth, although it is quite evident that education confers an advantage only on individuals who get more out of it than other individuals and would cease to be an advantage if all got the same amount" (p. 114).

2. Ayres refers to a concept as introduced by Adam Smith and still accepted by "[orthodox] economists" that specialization and division of labor are limited by the width of the market. This is equivalent to saying "that commerce is primary, and that industry is secondary and derivative. . . . This proposition is ridiculous. . . . The exact opposite of this proposition is clearly and incontestably true." Clearly, what enters the market must be made before it can be bought and sold. (Pp. 88-89)

3. The "supposition that 'labor' is the sole creative agent of industrial production" is presented for analysis. The complete refutation occupies a moderate sized paragraph, and is accomplished by the single and original ingenious device of pointing out that "even some very big businessmen work hard and perform important and even indispensable functions of organization and decision." Ayres does not stoop to the traditional method of alleging that other factors of production might also contribute. (Pp. 91-92)

4. In thinking of depression, "the question, 'What becomes of all that money?' is certain to arise in the mind of the reader. No one knows where all of it goes." Ayres offers three suggestions: part goes into hoarding, part into buying inflated securities, and part goes abroad. Mr. Ayres' original approach is again reflected in his omission of the cliché that most economists would have suggested here—that of credit contraction. (Pp. 143-144)

5. Discussion of the quantity theory of money constitutes a noteworthy contribution to monetary theory. He denies that large amounts of money in circulation are a causal factor in inflation. The oft-cited cases of "'galloping

inflation' " in Germany and China did not result from increases in the quantity of money. As "only brief reflection" will show, it is "obvious and undeniable" that the inflation resulted rather "because the existing government [was] 'coming apart at the seams'" (p. 241). Similarly, if money were to be sprinkled from airplanes, it would not be the quantity of money which would cause inflation, but the way in which it was distributed. In this case the method would "spread the conviction throughout the community that its government was crazy; and this might lead to 'galloping inflation'" (p. 243).

6. "All economic thinking postulates planning, and has always done so" (p. 186).

7. "A military program of any kind . . . makes no contribution whatever to the productive capacity of the economy" (p. 178). But "a military program does indeed act as an economic stabilizer" (p. 179).

8. "A 'capitalist' . . . is one who by virtue of possession and exercise of money power is believed to be an agent of industrial progress" (p. 120). This is the only definition of this term given.

9. Mr. Ayres rejects the idea that capital, as savings out of past production, makes any contribution to production. "The truth is, we have known for some time that economic growth is self-financing." New projects can be financed by creating money "quite literally, out of thin air." The existence of the new plants then itself justifies the creation of the money. (Pp. 114-117)

This collection of excerpts, which could easily be multiplied several times in the same vein, makes it clear that Ayres is on sound ground when he refers to "a formidable body of economic thinking from which this book is a departure." As noted previously, this characterization of the book by the author himself, applies equally well to its over-all organization.

ALFRED KUHN

University of Cincinnati

A Scholar in Action—Edwin F. Gay. By HERBERT HEATON. (Cambridge: Harvard University Press. 1952. Pp. vii, 260. $4.25.)

Rare indeed is the great scholar and teacher who becomes the subject of a discerning and inspiring biography. Such is the lot of Edwin F. Gay, one of Harvard's most famous economic historians. *Festschrifts*, often containing disjointed papers of varied value, are fairly common, and indeed Gay was presented with one of these in 1932. It is quite another thing to be able to enter into the inner mental life of a first-rate intellect. This Professor Heaton has enabled us to do in a book of unusual charm prepared for the Friends of Edwin F. Gay. Fortunately, Gay was a careful note taker, an indefatigable letter writer, a diarist, and a man of affairs, and from the voluminous records remaining the author has found ample material with which to work. Because of Heaton's vivid and understanding treatment of the problems which beset the student and scholar along his path from the beginning of graduate work to the achieving of the status of emeritus professor, or "grand old man," this study should appeal to younger men seeking to make careers in economics as well as to those who sat under Gay or otherwise came under his influence.

Edwin Francis Gay (1867-1946) had one of the most remarkable careers

in American economics and academic business administration in the first half of the present century. After completing his undergraduate work at Michigan he spent over twelve years in graduate study, financed by a small inheritance, in the great universities of Germany, Italy, Switzerland, and England. Starting as a student of mediaeval ecclesiastical history, he concluded with the study of economics and economic history, in which he came particularly under the influence of Wagner and Schmoller. To many American professors whose graduate work has been narrowly specialized and whose degrees have come with the speed and certainty of an assembly line, Heaton's chapter on "A Scholar in the Making" will make fascinating reading. It was Gay's long and diverse wandering in many fields of knowledge in many countries which was later to give his lectures such great scope and brilliance.

Heaton's treatment of Gay's career is equally rewarding. First we sample the trials and uncertainties of the young instructor and junior professor on the Harvard economics staff, to which he was appointed in 1902 and of which he ultimately became acting chairman. More interesting is the account of his years as the first dean of the Harvard Graduate School of Business Administration, 1908-17, a post which called for promotion, programming in an untried field, recruitment of a new type of personnel, and superb begging. The author has scarcely scratched the surface of the history of the transformation of business from an art to a profession, but his comments on Gay's objectives and program will be valuable to those interested in training young men for active careers in business. It is interesting to note that although he had no business experience, a fact which he deplored, his broad training in Germany, where academic study and practical administration were more closely allied than in the United States, fitted him well for this post.

There followed still more active years. In World War I, Gay became director of the important Division of Planning and Statistics of the Shipping Board, and later a member of the Board. He also was made a member of the War Trade Board, and finally acted as organizer and director of the Central Bureau of Planning and Statistics. These were important positions in which Gay attempted to bring rationality, singleness of purpose, and statistical control into the war effort. The author has vividly described the cross-currents, conflicts, and frustrations of that period in terms meaningful to those familiar with similar recent experience. The passages on the struggle to eliminate unnecessary but profitable commercial cargo movements and thus free ships for allocation to the military are especially good. Following the war, Gay was invited by T. W. Lamont to take over the position of editor and business manager of the New York *Evening Post,* a declining and nearly bankrupt newspaper. In this task of rehabilitation Gay was unsuccessful, at least by financial standards. The author deals critically and fairly with this somewhat painful episode. Then in 1924 came Gay's return to the Harvard "squirrel cage" as professor of economic history. As side interests, of which Gay had many, we got glimpses of his activities as one of the founders of the National Bureau of Economic Research and of the Council on Foreign Relations. From all this we see what Heaton means by "A Scholar in Action."

Among the interesting passages are those in which the author comments on

Gay's failure to produce any book, and on his fatal dual love for pure research and active life, with the consequent inability to get down to writing. The book also raises many questions about the adequacy of both European and American advanced training for the type of active life followed by Gay. Thus on many accounts this is a thought-provoking study which should be of great interest to the profession.

JOHN G. B. HUTCHINS

Cornell University

Catalogue of Adam Smith's Library. Edited by TADAO YANAIHARA. (Tokyo: Iwanami Shoten. 1951. Pp. ix, 126. Yen 350.)

The titles of the books in Adam Smith's personal library have been of especial interest to students of economic thought since they were first catalogued by James Bonar in 1894 for the Economic Club (*A Catalogue of the Library of Adam Smith,* London, Macmillan and Company, 1894). A second edition prepared by Bonar in 1932 for the Royal Economic Society was superior to the first edition both in accuracy and in coverage.

It is familiar knowledge that Smith's personal library was willed to his cousin, David Douglas, later Lord Reston. Lord Reston willed the books to his two daughters, Mrs. Bannerman of Edinburgh and Mrs. Cunningham of Prestonpans. The Bannerman collection has remained intact and is now at the University of Glasgow. The Cunningham collection was divided and the largest portion went to Professor R. O. Cunningham, once on the staff of Queens College, Belfast, who presented a number of Smith's books to the college. After his death in 1918 a large number of his own books, including some with the Adam Smith bookplate, were put up for sale. The volume under consideration deals with a portion of the Cunningham collection.

In 1920 Professor Inazo Nitobe bought in London the advertised list of Smith's books offered for sale by the Cunningham estate, and presented them to the Faculty of Economics, University of Tokyo. The titles of the Japanese-owned books were identified by Bonar in his *Catalogue* with the letter, "J." Although the Bonar compilation is quite accurate, subsequent corrections have been made in some of the items.[1] Bonar, in preparing the Catalogue, had to depend upon the list supplied by Professor Kawai which was not completely accurate. In the second edition of the Catalogue he was able to add some 20 items and make additional corrections.

One item in the Bonar *Catalogue* intrigued not only the editor but many others. In the second edition there appears the entry, "A Catalogue of Books belonging to A.S. [*sic*] 1761, f.4 1" (p. 174). Bonar referred to this item as "one of unique value." He further adds, "This list made either for or by Adam Smith himself, would show what was in his library at that date, when

[1] Claude Jones, "Adam Smith's Library—some Additions," Economic History Supplement, *Econ. Jour.,* June 1940, IV.

C. J. MacGarvey, "Notes on Adam Smith's Library and the Bonar Catalogue of 1932," *Econ. Jour.,* June 1949, 259 *et seq.*

he was Professor at Glasgow and had published the Moral Sentiments, but no book in economics" (p. 214). The item has aroused the curiosity of many British and American scholars. Dr. Bonar himself states, "Perhaps our Japanese friends will satisfy our curiosity in this matter" (p. 214). The mystery of the date of publication was cleared up by the late Professor W. R. Scott of the Univerity of Glasgow who secured a photographic copy of the manuscript and discovered that the date was 1781 instead of 1761.[2] The mystery of the contents of the volume has been cleared by "our Japanese friends" in the volume under review, which supplies the missing information on the contents of the Smith library and presents the final corrections to the Bonar list of the books in Japan. The Faculty of Economics collection includes 141 books or entries (308 volumes) of which 62 books or entries (98 volumes) are in English, 34 books or entries (43 volumes) in Latin, 28 books or entries (92 volumes) in French, 15 books (73 volumes) in Italian and 2 books (2 volumes) in German. The subjects cover a wide range of philosophy, literature and poetry, politics, history, geography, religion, natural history, art, language, mathematics, etc., but there is no book on economics save Smith's own chief work and a German translation thereof.

An appendix, which is probably of greater interest, reveals for the first time the contents of the item, "Catalogue of Books belonging to Adam Smith, Esquire, 1781." This was prepared by or for Smith and written in longhand not by Smith but probably by a clerk. It contains about 1120 books or entries (2300 volumes). Professor Yanaihara has carefully checked and listed the page reference for each item against the Bonar *Catalogue*. The student will discover that many items in the catalogue of 1781 do not appear in the Bonar volume.

Smith used a curious method of identifying and locating his books in what he called, "Divisions." The 87 sheets of the handwritten book list the items as they were located in his own book cases such as in the "Upper Row" or "Lying on the Top," "Left Hand Book Case, Shelf 1st," "Right Hand Book Case, Second front Row," "Book in Locked Press Left Hand Window Book Case" and so on. The entries are brief and contain only the name of the book, number of volumes if more than one, but no date or place of publication.

In making this information available to the world of scholars "our Japanese friends" have rendered a distinct service. Persons owning books with the familiar Adam Smith bookplate will be able to authenticate the volumes by referring to the Japanese publication. The complete list of Smith's volumes provides an excellent view of the materials which influenced his own thinking and which were of current interest in the eighteenth century.

Economic History; National Economies

A Concise Economic History of Britain, From Earliest Times to A.D. 1750. By SIR JOHN CLAPHAM. (Cambridge: Cambridge University Press. 1949. Pp. xv, 323.)

Sir John Clapham's last years were occupied not only with his history of the Bank of England but also in writing an elementary general economic history of Britain. This volume, taking the story to 1750, was virtually completed at the time of his death. The final volume, barely begun by Clapham, has been turned over for completion to W. H. B. Court. The fact that the two volumes represent largely a formalization and development from Clapham's famous lectures, which Cambridge heard for more than a quarter century, makes Court's task the more possible. John Saltmarsh, Clapham's pupil and colleague at King's College, has seen the present volume from typescript to final text with evident care and sympathy.

Elementary teaching and writing, taken seriously, is a more rigorous discipline than common thought would allow. It forces the teacher to set out his views on the large issues and to reveal in his proportioning and emphasis the fundamentals of his thought. No single work of Clapham's exposes more clearly than this volume the character of his contribution and interest in economic history.

The generation of economic historians before Clapham, notably the Germans, Cunningham, Rogers, and the Fabians, were all reacting, in different ways, to the dominance of classical economics over public policy. They were pamphleteering, in a sense, against the internationalist, free-trade, and domestic laissez-faire biases built into the formal assumptions of economic theory as conventionally formulated, say, between 1815 and 1870. Clapham was not wholly disloyal to this tradition in the second generation of which he was so commanding a figure. His famous "empty boxes" article, on the inadequacy of the Marshallian treatment of the cases of increasing and decreasing returns in particular industries, was certainly one of the more pertinent and effective interventions of an historian in economic theory. His principal concern, however, was not to set the economists straight or to influence public policy in any direct way. He aimed to tell the story of how British men and women earned their living over the centuries. If any dominating motivation comes through Clapham's work, it is a profound affection in detail for England and those who made their lives within it; even the Irish, Scotch, and Welsh are a little foreign to him. And there is no more eloquent statement of the dignity of economic history as a means of tribute to land and people than the one-page introduction to this volume.

The directness and even literalness of Clapham's interest in the economic process made him primarily an historian of the techniques and organization of production and trade. He is a narrator of the changing state of the economic arts, and of the institutions which incorporate them. He set out to establish how things were produced and traded, rather than why. Read closely, it is evident that Clapham speculated on the major issues of causation in British economic history; but his wisdom is articulated implicitly, within

austere self-imposed limitations, and embedded cryptically in observations on particular situations. Clapham's dislike of abstraction, which contributes to a rare strength and justness in his prose, also narrowed the range of materials and problems with which he was prepared to deal.

The present volume starts with brief chapters on prehistoric Britain, the Roman era, and the Saxons and Normans. With remarkable economy he summarizes the nature of the evidence available to the historian, and then sketches the character of the British economy in terms of agricultural techniques and land-holding institutions, the extent and methods of nonagricultural production, and the character of foreign trade, if any. Then follow the two major sections of the book, running, respectively, from 1100 to 1500, and from 1500 to 1750. Each of these sections treats, in turn, agriculture, industry, and, grouped together, trade, public policy, and finance. Extremely brief commentaries on population and, in the case of 1500-1750, prices precede the two major divisions into which the account is divided.

This division of the narrative fitted naturally the descriptive and institutional character of Clapham's interest. On the other hand, it denied him the possibility of imparting a sense of the living interaction among the parts of the economy or of the movement of the economy as a whole, over time. Clapham's structure automatically carries with it the impression that, in each sector of the economy, the important forces making for change lay within that sector, rather than outside. It is not accidental that the discussion of population movements and price trends is perfunctory. Modern studies which have refined our knowledge of the complexities and regional differences in landholding and agricultural techniques are woven in fine balance into the book, as are other institutional pieces of research; but some of the analyses which probe at the process of transition of the British economy from a medieval base to the commercial capitalism which emerged in the late seventeenth and eighteenth centuries are slighted.

Clapham was a rare and fortunate scholar. His last years saw him still at the peak of his powers, both in the history of the Bank and in the present volume. The limitations of the latter are those which he accepted in marking out his whole wide field of endeavor. He sought out and mobilized under the highest standards of scholarship enormous areas of factual knowledge and laid foundations in modern British economic history which are likely to remain solid. There is no cause to complain of his work in general or of this excellent survey; but there are still jobs to do and questions to answer.

Mr. Saltmarsh, in his editorial note, remarks, "I believe that those who knew and heard him will sometimes hear again, as they read, the tones of his voice." Although by no means a collection of old lectures this book remains a highly personal work. Through it comes strongly a man's intimate knowledge of his nation's countryside; a yeoman's pride in the early dissolution of feudal ties with arrangements based on the rights of individual men; a wholesome, ill-concealed pleasure when Britons outdo foreigners. Clapham brings to the evolution of a great nation's economy all the virtues of attachment which usually belong to a regional historian or antiquarian. It is pleasant to

think of a generation and more of Cambridge men being brought up on Clapham's version of the story; and it is good to have it between covers.

W. W. Rostow

Massachusetts Institute of Technology

The Theodosian Code and Novels and the Sirmondian Constitutions. A Translation with Commentary, Glossary and Bibliography. By Clyde Pharr, in collaboration with Theresa Sherrer Davidson and Mary Brown Pharr. (Princeton: Princeton University Press. 1952. Pp. xvi, 643. $20.00.)

The massive crisis of our times has provoked a searching re-examination of the passing of Greco-Roman civilization, and an immense contribution to that end has been made by this monumental translation—the first to be made—by Professor Pharr and his associates, of the most important contemporary source for the death-throes of the Roman Empire. For, since Jacques Godefroy's edition of the Theodosian Code and the post-Theodosian legislation, published in 1665, with its masterly and still indispensable commentary, the exploitation of the vast storehouse of material contained therein has been largely reserved for specialists in Roman law and legal history. Hence, this volume—ten years in the making, and the beginning of a project to collect and translate all the source materials of Roman law—has opened up a new era of research in this prime source for the legal, administrative, political, economic, social, military and ecclesiastical history of the fourth and fifth centuries. Containing in the Code proper an official compendium of all general imperial enactments from A.D. 312-438, together with subsequent legislation in uncondensed form to 468, this body of laws spreads before our eyes a firsthand picture of one of the momentous transformations of human society.

The reader will want, first, assurance of the reliability of the translation, which has been prepared with scrupulous pains, an immensely difficult task because of the corrupt text and numerous ambiguities. Not to prejudice the translation by editorial interpretation, and to preserve the turgid flamboyance of the Byzantine officialese, Pharr has made the translation as literal as English will allow. Yet it seems to this reviewer that the principle of literalism has been applied to excess, so as to appear in many places supererogatory. The reader will also want to know that the volume is provided with a spirited introduction by the New York attorney C. Dickerman Williams, an outline of Roman history (excessively brief, with inadequate attention to the history of the fourth and fifth centuries), a mine of information in the glossary, an exhaustive index, and a map of the Roman Empire.

Mr. Williams in his introduction warns us that "we shall ignore the Code at our peril." His exhortation is evoked by the deadly parallels between the societal patterns revealed in the Code and those of our own age, and between the economic and social measures resorted to in order to stem the collapse of the Roman Empire and the steps taken by modern statesmen, and by the fact that western Europe disintegrated shortly after the promulgation of

the Code. Paradoxically, the Byzantine Empire in the east survived for a thousand years under the same regimented economy and social order. Moreover, Rome did not fall in a day. For all the basic phenomena institutionalized during the decline were inherent in the fundamental contradictions of the whole society and had already begun to manifest themselves in the mounting economic crisis at the end of the first century. It is a remarkable fact that, critically weakened in the internal economy and living constantly under the shadow of barbarian hordes without, the emperors and the ruling classes were able to sustain the basic integrity of the empire for centuries.

Beginning with the general crisis of the empire in the third century A.D., the inhabitants of the Roman world lived under a permanent state of siege for centuries. Faced with a critical scarcity of productive labor due to depopulation and the allocation of large numbers to the military forces and bureaucracy, a staggering agrarian crisis, disruption of the free flow of commerce, inflation, sharp rise in crime and brigandage, the emperors mobilized the entire population of the empire in a completely regimented garrison-bureaucratic-clerical state. This social order was not the realization of a political ideology, but the frantic adaptation of the reduced resources of the empire to the goal of survival of the ruling classes. And to the inhabitants of the empire, living under a system of rigidly controlled economy, almost confiscatory taxation to meet the fiscal needs of the central administration, and state compulsion to maintain production and services, the emperors Arcadius, Honorius and Theodosius could pathetically proclaim in 406, when the survival of the empire under the blows of the barbarians seemed in doubt, "We summon to military service all men who are aroused by the innate spirit of freedom."

In his commentary Pharr reiterates the view that excessive taxation was perhaps the most important factor that resulted in the collapse of the empire in the west. But the emperors had little choice, for, when the Roman state could no longer meet its fiscal needs as it had done in the early stages of its march to world power by booty in foreign wars, it resorted to heavier demands on the population, both in taxes and compulsory unremunerated labor. In the absence of a concept of a national debt in antiquity, the emperors oscillated between oppressive taxation, extraordinary assessments, and periodic remission of taxes when the economy seemed at the breaking point. The greater part of this tax burden was shifted by the powerful and privileged landowners to the backs of the lower classes, who were steadily impoverished, and whom the emperors were powerless to protect from the venality and rampant corruption of the bureaucracy and the landed military ruling class. Two of the concomitant effects were the rapid polarization of society into rich and poor and a drift to natural economy after a thousand years of brisk money economy in the Mediterranean.

To guarantee necessary labor and revenue, the concept of compulsory public services inherent in the ancient state was drastically stepped up, and social mobility was almost completely eliminated by a regime of social status and hereditary occupations in all spheres of the economy and administration. In this empire-wide conscription of labor and capital we see, for

example, the beginnings of rural serfdom, the concept of membership in rigidly controlled state guilds, and the resort to what were virtually confiscatory capital levies on moderately wealthy members of municipalities. One drastic measure contained in the Code is the branding of members of the hereditary guild of arms makers to prevent their desertion from the imperial armaments workshops.

But, in fact, the centrifugal tendencies in the empire, under the critical international conditions, the insupportable burdens imposed by the state, and the incredible corruption, were irresistible. There occurred, as the Code reveals, what amounts to wholesale desertion from the society, in the form of flight to the privileged clergy, the civil services, the army, the wilderness, brigandage, the barbarians, or to the protection of the powerful landed military nobility, who competed with the state for the labor of peasants and artisans, and before whom the emperors were often powerless. The empire could not have survived as long as it did without the assistance of these men, the feudal barons of the next stage of European society, and yet their growing power was one of the most important factors in the breakdown of the central authority.

Economic historians and students of the structure of the "closed" economy will welcome this accessible version of a prime source for what Gibbon, idealizing the Pax Romana of the second century, was moved to call "the greatest, perhaps, and most awful scene in the history of mankind."

MEYER REINHOLD

Brooklyn College

The Bias of Communication. By HAROLD A. INNIS. (Toronto: University of Toronto Press. 1951. Pp. ix, 226. $4.50.)

According to the preface, this collection of papers further develops the thesis of *Empire and Communications,* published in 1950. Having read both works, the reviewer is still unable to decide which of various related themes is meant. The uneven pace and scope of social development are in themselves a commonplace assumption rather than a thesis to be debated. We come closer to a thesis in the "emphasis" on communications as determining objects of human attention and the "suggestion" of the converse.

A concept of monopolies of knowledge which dissolve to make way for new ones as new mediums of communication appear runs through these books and other writings of the same author. It amounts to an innovations theory—almost to a technical-innovations theory—of cyclical growth, the political units stressed largely sharing the fate of the monopolies. Speaking and writing tend to be active, listening and reading passive. Listeners and readers (particularly the latter) tend to be multiple. The multiplicity has increased with the appearance of paper, of printing and of improvements both in printing and in means of circulation. Moreover, reading is for the most part an indirect contact, with lags in time and differences in space which have increased with technical improvements. An oral tradition, here associated with common law, informal procedure and vernaculars, is held to be more flexible and conducive to freedoms. However, the written tradition has generally won

out in the end. Radio diffusion, first of the voice and then of gestures as well, seems likely to bring a whole course of development to an end. A new long cycle which appears to be emerging is fraught with great dangers to the individualism, the freedoms and the flexibility which Professor Innis treasured.

Another general theme, specified by the paper which gives the volume under review its title, is the bias of communication. The sharpest statement of it is at the close of the 1950 work. In brief, concentration on one medium of communication tends to overweight the development of a society either on the side of space and political organization or on the side of time and religious organization; but a second medium serves as a balancer, making for imperial growth and durability. Parchment added to papyrus in the Byzantine empire illustrates the balance. The displacement of parchment by paper in the West, introducing a cheap and copious but perishable material, is said to have timed a shift from a Church monopoly of largely sacred writings in a dead language to varied writings in vernaculars, and from ecclesiastical to political organization.

Shorn of their rich historical trimmings for purposes of review, the two themes are here little better than caricatured. On the other hand, more of the complex fabric of argument would have raised more debatable points. Minor shifts of emphasis, order or illustrative material would shed doubt upon stated or clearly implied conclusions. This reviewer is unhappy about the general proposition that an oral tradition makes for flexibility. The clerical monopoly of literacy was far gone before the sacred texts were translated into the vernaculars, as Pirenne has noted, for example, in his study of the education of merchants. The Reformation could be characterized as an appeal from the authority of a flexible institution to that of written texts which carried the rigidity of age into any language. Theodore Collier used to ascribe whatever toleration emerged to a multiplying of sects which gave dissent the safety of numbers.

"Communication" has become an omnibus label for social relationships varying from simple, direct and merely practical transmissions between persons to the shifting continuity of institutions on a world scale and throughout human time. Between these extremes are gradations which involve differences in quality as well as in amount. Each ideology of the subject fills the chasm between communication as a definite act and communication as the historical continuity of mankind in its own way. Innis seems to have deliberately refrained from creating a systematic theory of history in the conviction—itself clearly stated—that his own time and society were no more exempt from bias than others.

Some of these papers are histories as distinct from the theory or the philosophy of history. The one entitled "Technology and Public Opinion in the United States" is a highly informed and intelligent sketch of the history of publication. It should be of interest to any student of American history.

University of California
Berkeley

The Idea of Progress—A Collection of Readings. By FREDERICK J. TEGGART, with an introduction by GEORGE H. HILDEBRAND. Revised edition. (Berkeley and Los Angeles: University of California Press. 1949. Pp. xi, 457.)

There is a special value in approaching the history of the concept of progress through selections from leading thinkers. No systematic analysis can bring out in sufficient relief the profound differences in the settings which provided the background for these concepts of change and progress over so many generations. The texts themselves, even when short, serve as a constant reminder of the underlying differences in factual information and speculative thought. The introduction furnishes an indispensable guide and draws the selections together into an organic whole.

Although the philosophies of the classical period were inconsistent with any comprehensive concept of progress, basic elements of the idea emerge at an early date. If we pass over the doctrines of Hesiod of degeneration from a golden age, we find a substantial development of a concept of cycles of growth which survived in much nineteenth century sociology. Stated in somewhat different forms by both Plato and Aristotle the concept of cycles of social and cultural development remained the predominant analysis of change in classical antiquity.

It is noteworthy, however, that Thucydides and Lucretius present clear statements of a cumulative increase in knowledge and skill as the outstanding feature of social development. This idea was an important element in the thought of Augustine, who explicitly conceived social development as the embodiment of all the potentialities of the human mind. In the City of God, however, these ideas were overlaid by emphasis upon a Divine Plan which defined the ends of social life. Augustine gave much attention to the problem of freedom of the will, but his doctrine interpreted social development as a fulfillment of the Divine Plan.

The modern formulations of these concepts were hardly more than fully secularized versions of the Augustinian doctrine. The new view is clearly stated by both Pascal (1647) and Fontanelle (1688) though the implications are not very adequately expressed until the time of Turgot and Condorcet. The optimistic tone of eighteenth-century liberalism was carried over into this field of thought, and this concept of progress became a primary element in the philosophy of liberalism.

This development culminates in the work of Darwin. With him, systematic exposition in the introduction is likewise brought to an end. There are, however, several pages of stimulating reflections upon the present loss of faith in the liberal optimism of the eighteenth and early nineteenth centuries. There is no reference to the revisions of the empirical philosophy that have been taking place since Darwin, and more particularly within the last thirty years. From these points of view it would be possible to give new emphasis to the concept of cumulative increase in knowledge and skill.

The analysis of these phenomena should be separated from the biological problems of individual and social growth. If such a position were developed, the history of these concepts would present a record of a persisting dilemma of

choice between the somewhat restricted concept of cumulative mental achievement individually and socially, and the broader generalization which included all forms of quantitative growth. The classical concept of cycles is properly speaking a concept of growth rather than a concept of progress. It was, therefore, consistent with the conviction that change was incidental and not very important. In modern sociologies concepts of cycles, or even of nonrepetitive stages, became a source of genuine confusion.

Different kinds of growth require different techniques of analysis and concepts of growth cannot happily be given a melioristic significance. It is essential to distinguish between the cumulative phenomena of the mind and organized mental activities and the growth phenomena of biology whether individual or social. Even a very brief reference to these problems would give added meaning to the history of these concepts.

International Aspects of Indian Economic Development. By D. T. LAKDAWALA. (New York: Oxford University Press. 1951. Pp. 191. $2.50.)

Indian Economic Policy. SOHAN RAJ MOHNOT. (Allahabad: Friends' Book Depot. 1952. Pp. ix, 224. Rs. 6.)

International Aspects of Indian Economic Development is an absolutely correct descriptive title of this dispassionate and closely reasoned volume. The analysis is of a detailed type so that only the most general idea of its contents can be given. Most of the subject matter falls under two categories: (1) the place of foreign capital in Indian economic development and (2) how exchange policy and trade policy can aid economic development with India still honoring international commitments.

India must develop her resources rapidly to overcome the discontented poverty of her people and to keep ahead of the steadily mounting population. If the people are to raise their living standard by 40 per cent in two decades, an annual increase in national income of 3.78 per cent is called for. One of the ingredients necessary for such rapid expansion is capital investment. By an income-savings-investment approach and by the balance-of-payments approach the author estimates about 30 billion rupees ($6.4 billion) of foreign capital would be needed over a 20-year period to sustain this rate of growth. It may be noted that this is close to the rate of foreign capital requirement envisaged in the official Five Year Plan recently published by the Indian government. It is estimated that about Rs. 12 billion is needed as equity capital and the rest as loans. The author believes that such quantities of foreign capital will be forthcoming since developed nations have recently become more sympathetic to industrialization of underdeveloped areas, and since this changed attitude has been institutionalized in the International Bank for Reconstruction and Development, the Export-Import Bank and the Economic Cooperation Administration (now Mutual Security Agency). However, to avail herself of this capital India must accept conditions of capital-granting countries including guarantee of exchange convertibility,

nonlimitation of profits on foreign capital (except in so far as domestic capital is so limited) and granting substantial control to foreign equity capital. He estimates that amortization and interest on such capital would amount to about 19 per cent of India's exports and would thus create a difficult but not insuperable transfer problem.

An exchange policy and trade policy are needed to insulate India from foreign depressions and to prevent an unfavorable balance of payments induced by the program of rapid foreign investment. Yet such policies should be adjusted to honor India's actual or possible commitments in the International Monetary Fund and International Trade Organization (in future). Conditions are discussed in which currency depreciation would and would not be helpful. The author suggests that the I. T. O. Charter should permit, but restrict, a modified multiple exchange rate system. He advocates taxes and subsidies on imports and exports as the most effective and least disturbing type of trade policy. Quotas are thought of only as a last resort and it is felt that India has little to gain from state trading.

Parts of the book are closely reasoned, yet a good balance is kept between theory and its application to India's specific needs. Diagrammatic presentation of certain aspects of the theoretical discussion will be found helpful. The outlook is definitely internationalist, which is not easy to achieve in a country needing such drastic domestic development. The last year or two has shown the author to be over optimistic about the possibility of India obtaining large capital grants. His optimism as to the imminent reality of the I. T. O. was unfortunately unfounded. This book is a welcome addition to the literature on India's economic development.

Indian Economic Policy is a tract for the times. Two great pleas stand out predominantly: (1) the need for more thoroughgoing economic planning, and (2) India's foreign economic policy must be subservient to her domestic needs for rapid industrial development.

The present Five Year Plan of the government of India proposes to increase land irrigated from 48 million to 57 million acres and increase food production by 7 million tons thus increasing the basic grain ration from 12 to 14½ ounces per person per day. It plans a development outlay of 18 billion rupees over a five-year period which may be compared to present national income of 87 billion rupees. This plan is hailed as a "laudable beginning" but is roundly criticized for being merely a plan for economic development rather than a full-blown plan for all economic activity. The author's most basic criticism is that present Indian planning is designed to operate within a framework of *laissez faire* using price incentives toward planning goals. He advocates a more rapid transition toward direct state controls, nationalization of new industrial sectors, exchange control and mechanization of large-scale cooperative farms on a voluntary-compulsory basis. At the same time the author points out the dangers and abuses to which such direct controls are liable, but considers that, if democratically administered, they are to be preferred to price incentives as a tool of economic planning.

"Conceding that the *status quo* has to be maintained," the author agrees

that the Five Year Plan "is a sincere effort for coordinated economic development of the country" (p. 60). However, he offers numerous specific criticisms. He feels that an overemphasis on agricultural and a neglect of industrial development will "prevent the plan from serving as a stepping-stone for further progress" (p. 52).

Although India desires to maintain friendly relations with other nations, he sees the primary function of her foreign economic policy as being to help realize domestic planning goals. He advocates that India more rigidly control her foreign trade, and that a much wider range of industries be granted tariff protection as an aid to industrial development. Exchange control is but one of the methods needed to help India overcome her unfavorable balance of payments; other advocated measures include import quotas, export subsidies particularly on goods earning hard currencies, bilateral trade agreements and judicious use of state trading.

There are chapters on the need for population control, the need for fiscal policy and specific controls to assure full employment, a survey of recent labor legislation in India, a short chapter on the place of agriculture in India's development plans, and a discussion of the usefulness of the public corporation as a tool of national planning.

About half the chapters have appeared earlier as articles in various Indian journals; as the author says this "has robbed the story of its continuity and spontaneous sequence" (p. vii). One major inconsistency in point of view is apparent to this reviewer. The majority of the chapters, while advocating a moderate socialism, are careful to point out the need of a government policy to assure continuing and adequate incentive in the private sectors of the economy. However, Chapter 3, which is a criticism of the Five Year Plan, ignores the problem of incentive almost completely. He calls the investment envisaged under the plan "meagre" but it is difficult to see where he would seek the additional capital. Although he advocates larger government borrowing (p. 43), he elsewhere warns that further deficit financing will lead to disastrous inflation (p. 42). We are told that taxes are too high and should be reduced, primarily as an incentive to industry. The need for foreign capital is realized but the author is not sanguine as to the amounts forthcoming in the immediate future. Thus the reader is left rather confused as to the method of drastically increasing the rate of planned investment. In the opinion of this reviewer, the author places too much emphasis on the need for industrial development at the expense of neglecting agricultural development.

In spite of these shortcomings, this volume is a good introduction to commercial and economic thinking in India concerning her most basic problems of economic policy. The style is interesting and there is a facile blending of economic background and political realism.

Swarthmore College

Economic Systems; Planning and Reform; Cooperation

The Soviet Economy during the Plan Era; The Soviet Price System; and *Soviet Prices of Producers' Goods.* By N. JASNY. (Stanford: Stanford Univ. Press. 1951 and 1952. Pp. xi, 116; x, 179; vii, 180. $2.00, each.)

Mr. Jasny's impressive trilogy is a major attempt to pierce the veil of manipulated prices which the Soviets have drawn across the structure and development of their economy. If this work is to be viewed as an integral whole, it is probably best to read the three volumes in the inverse order of their appearance, starting with *Soviet Prices of Producers' Goods* and finishing with *The Soviet Economy during the Plan Era.* This course will lead the reader from the particular to the general, and should ensure that the bold strokes in which the final picture is drawn will not become engraved in his mind more firmly than is warranted by the nature of the methods of estimation which had to be used.

The central and most challenging conclusions of Jasny's work, as presented in the last-mentioned volume, spring from his revaluation of the Soviet national income and its components in terms of United States dollars at 1926-27 prices. This somewhat hazardous undertaking involves three distinct steps:

1. The estimation of various aggregates in terms of current prices, whether government-decreed or freely formed on collective farm markets.
2. The deflation of these values to the *Soviet* price level of 1926-27 by means of a number of specially constructed price indexes.[1]
3. The conversion of the figures so obtained into United States dollars of 1926-27 at rates of exchange giving parity of purchasing power over the various classes of goods involved.

In this general scheme Jasny's two books on the price structure fall into place as expansions of the second step, though in sheer volume and weight of evidence they transcend this rôle and become independent studies in their own right. The material brought together and sifted in these volumes is to be welcomed as a massive contribution to the field of Soviet studies. Ever since 1930, when the Soviets discontinued the systematic publication of price statistics, Western students have had to grapple with a type of problem more amenable to the mental equipment of cipher clerks than to the tools of economic analysis properly so-called. The messages intercepted were found to be in two main languages: the language of "stable rubles," dealing chiefly with gross output, labour productivity, and national income; and the language of current rubles, used in references to the budget, retail sales, investment, and fixed capital. Much effort has been expended on translating particular messages from one language into the other, and, occasionally, into straightforward English, but Jasny's study goes beyond this and evidently aims at providing us with a working dictionary.

It is not easy to say how far he has succeeded without having access to the very dispersed and recondite material used. As he relies mainly on price

[1] The official "stable ruble" figures purporting to be based on the 1926-27 price structure are rightly discarded as unduly "processed."

data for individual commodities, it requires something of an act of faith to accept his generalizations concerning the price-trends of whole industries and economic sectors. We are told, for instance, that since there are insufficient data to permit the computation of the weighted average price of all fuels used in boilers, "the trend of the prices of Donbass coal may be taken as fairly representative of the price-trend of all such fuels" (p. 54). This may be so, or it may not. While it is readily conceded that some boiler fuels rose more in price than Donbass coal and others less, the reader is in need of some assurance that this is a rabbit of respectable antecedents, and not out of a hat. Though undoubtedly of central importance in the country's fuel balance, Donbass coal accounted for less than half the calorie consumption of heavy industries in the early 'thirties (the percentage for light industry was less than a third), and its importance declined steadily in later years. The most summary Soviet calorie-conversion tables list some thirty types of coals alone, with at least 20 distinct calorific values and presumably as many divergencies in ash content and other qualitative criteria. This suggests a bewildering multiplicity of prices, among which only the eye of faith can pick out a suitable representative without an extensive knowledge of the performance of other candidates. Jasny's admirable exposure of the chaotic state of Soviet price planning in other parts of his work shows up the widely divergent and erratic price movements of close substitutes, and so does little to encourage complicity in his sanguine behavior. To my mind the transition from individual to composite price trends needs the support of a more aggregative analysis, such as comparison of the expenditure on fuel by various users with the total calorie-content of their fuel consumption. These data are available for a number of prewar years and could probably be collected and sifted with a fraction of the effort that went into Jasny's price compilations. In the only case where this method is extensively used, the case of rail transport, the results obtained diverge from Jasny's inductive generalizations; unfortunately he contents himself with stating the discrepancy and expressing the hope "that further analysis will solve the puzzle" (p. 56).

A similar source of uneasiness is the estimation of construction costs. Again the procedure of compounding individual price series by largely intuitive methods results in a trend markedly different from that yielded by a more aggregative method.[2] Jasny registers surprise at the discrepany, but comforts himself and his readers with observations on the general obliquity of Soviet accounting methods which "it would be absurd to call . . . 'statistics' " (p. 24). While one may agree with this view in more than one respect, it is hardly reassuring to find that the emphasis it receives at Jasny's hands varies in proportion to the divergence of Soviet official data from his own findings. It should be said in fairness, however, that many of the methods and sources which throw doubt on Jasny's indexes are explored and stated openly by the author himself.

The companion volume of the series entitled *The Soviet Price System* deals

[2] Comparison of parallel official valuations of fixed capital at the nominal prices of different years.

with three main subjects: an extension of the survey to farm prices and industrial consumer goods, an examination of that bugbear of critical analysts, the official "unchangeable" prices of 1926-27, and a review of Soviet national income accounting with some of its less-known tricks and foibles. In the survey on agricultural and general consumer prices, the descriptive portions give an excellent and much needed summary of the main lines of development, and the statistical illustrations appear to rest on a broader and more solid foundation than in the other price study. There is a summary appendix table giving the price movements of some thirty individual commodities for seven selected years between 1926 and 1950. To my knowledge this is the most extensive compilation of its sort to be published in the West, and there can be no doubt of its value as a work of reference. It is all the more regrettable that the author's method of aggregating these data into a price index for consumer goods as a whole bears all the marks of arbitrariness. Confusingly enough, this aggregation is carried out in the other volume of the series, *Soviet Prices of Producers' Goods* (pp. 18 and 19), where it appears in seminarrative form as an intermediate step in the estimation of a still more comprehensive price index (for industrial goods as a whole). The difference in intellectual climate between the scholarly and painstaking compilation of individual prices and the rough and ready guesses as to their conjoint movements, in the course of which much of the original information is discarded and the rest allowed to merge into a vague impression, detracts greatly from the high level of Jasny's work, and is apt to reduce our confidence in his method of selective price compilations as a tool of analysis in this field. Little comfort can be derived from various more aggregative checks suggested in the chapter on "phantom unchangeable 1926-27 prices." These are tainted by the same laxness and appear to be inconclusive.

The chapters on Soviet national income accounting are probably the most revealing parts of the book. Unfortunately Jasny's information here is secondhand; it is derived via Prokopovicz from a Soviet source of considerable authority[3] apparently not available in the United States. This explains why some of the most glaring manipulations of Soviet national income accounting are not mentioned, while others are perhaps given undue weight. Thus, for instance, the practice of counting the losses made in industry as part of industry's contribution to the national income, which may have caused considerable distortion in the early plan era (say up to 1936), is not mentioned. On the other hand, I am not convinced that the *total* yield of turnover tax is deducted from the net product of trade and imputed to industry. If this were true, it would be difficult to see why the Soviet source on national income referred to above should list the trade tax separately under that heading. Moreover, the size of the relative share of trade in the national income at current prices (9-15 per cent) would be difficult to explain if that tax were excluded.[4]

[3] I. M. Krasnolobov, "The Planning and Computation of National Income" (Moscow, 1940).

[4] The trade tax proper must be distinguished from the turnover tax paid by the State procurement organization (Narkomzag); with respect to the latter Jasny is probably right in assuming that Soviet practice imputes it to industry rather than trade.

The crowning volume of the trilogy is no doubt *The Soviet Economy during the Plan Era*. Here the results of the other two volumes are extensively used as tools of analysis. Estimates of total outlay on various items, such as munitions, military pay and subsistence, consumption and investment, are made for a number of years in terms of current rubles, to be subsequently deflated by the price indexes which Jasny considers to be severally applicable to them. The figures so obtained are then converted into United States dollars of 1926-27 in order to display the structure of national income through the years in comprehensible terms. The picture which emerges is a dismal one indeed. Private consumption is represented as having declined from three-quarters to less than a third of the national income between 1928 and 1948, while the share of defence expenditure appears to have increased from 2.5 per cent to close to 20 per cent. The lion's share is presumed to go to net investment (40.7 per cent in 1948, as against a mere 17.2 per cent at the start of the plan era). On this last point Jasny is in sharp disagreement with other Western analysts, such as Wyler.

The scarcity and poor documentation of Soviet statistics, which must be held responsible for the possibility of, and even necessity for, this type of estimate, makes it equally hazardous to disprove Jasny's findings without a research effort far beyond the scope of a book review. As a matter of general principle, the use of American prices of 1926-27 for Soviet national income computations extending as far as 1948 would seem to be of doubtful relevance. The margin of error involved in the estimates is of necessity so wide that the further step of converting the figures to American prices of, say, 1940 could not have materially affected the accuracy of the result, while the gain in significance and comparability with other estimates would have been considerable. International comparisons of economic structure in terms of national price systems are full of pitfalls and perplexities at the best of times, but when the spatial remoteness of the standard of comparison is aggravated by an equally alarming remoteness in *time*, the difficulties of interpretation begin to be quite serious. The best argument that Jasny could produce for his choice of 1926-27 dollars is probably the fact that the ruble-dollar exchange rate in that year was still operative, while it became nominal in later years. This is true, but hardly relevant to the significance of the final outcome. I cannot help feeling that a better hope for our understanding of Soviet economics lies in the direction of social accounting studies in terms of current rubles, with allowances for the abnormal structure of indirect taxes, depreciation rates, and profits. This would make the national income of the Soviet Union and the United States comparable in terms of *costs*, a far more objective criterion than the static consumer preferences implied in an esoteric price system.

Jasny's books deserve the closest study of all students of Soviet economics, in fact of anyone concerned with international comparisons and an over-all view of economic development transcending national frontiers. They deserve admiration as well, chiefly for the assiduity and patience which must have informed those massive and scholarly compilations, but in some measure also for the author's supreme confidence and resourcefulness in putting them to work in a good cause. These qualities must be highly rated in a subject

bristling with difficulties and frustrations, in which there is no room for the faint in heart. It is all the more regrettable, therefore, that as regards the final indictment of the planning system which Mr. Jasny has drawn up, this reviewer finds himself constrained, with all respect for the author's special pleading skills, to return a verdict of "not proven."

F. SETON

Nuffield College, Oxford.

Democracy and the Economic Challenge. By R. M. MACIVER. (New York: Alfred A. Knopf. 1952. Pp. 86. $2.50.)

In these five lectures, delivered on the William W. Cook Foundation at the University of Michigan, Professor MacIver provides a "liberal manifesto" calculated to help some in resisting the lure of the *Communist Manifesto* and, what is more important, to help others to understand the real values of the liberal democratic way of life. We need intellectual and spiritual rearmament as much as we need armament. MacIver's contribution is excellent; it is to be hoped that many other senior scholars will help in this work. "In these times," says MacIver, "it is not enough to hold aloft the banner of free enterprise. The cause for which men live, the flag for which they fight, must appeal to their hearts. Let us take this lesson from our adversaries. They offer to the Western peoples not only security but also a faith, and to the Eastern they promise not only land but a vision. . . . This vision is particularly necessary to win the loyalties of the young. We won't hold them, we certainly will not inspire them, if we make our case on the ground that capitalist enterprise is more efficient than socialist planning. . . . No, we must seek stronger and higher ground if we are to convince ourselves, still more if we are to seek to persuade other peoples that ours is the better way. That is why it is deplorable that in this country we are so superficial about our democracy. We do not appreciate the strength, the vitality, the depth and the breadth of the thing that makes us one" (p. 73).

In the first lecture the theme is the emergence of "private economic power" and its "historic role" in fostering the rise of democracy. The second lecture is concerned with the new rôle of the state as it turns to guide and canalise "private economic power." Very valuable in this chapter is the distinction between the welfare state, the socialist state and the communist state. The welfare state is "consistent with private economic power" and should be "welcomed as the surest protection against the perils of communist infiltration" (p. 30). The third lecture is on the "portent of Karl Marx." "The leading spirits of communism—in countries where it is not already enthroned—have espoused it not because of a detestation of capitalism but because for one reason or another they are at war with the society in which they live. . . . It is our own betrayal of democracy more than the shortcomings of capitalism that fills the communist ranks" (pp. 38-39). The fourth lecture discusses the question "whether a fully planned, centrally directed economy . . . can exist with the attitudes and the processes of democracy." Again there is emphasis on the difference between the welfare state and the socialist state. "The goal is not

socialism nor capitalism, nor any neat blueprint of economic organization. The goal is the freer and fuller life of man in his society, equipped with all the means that liberate his capacities" (p. 70). The final lecture is an appeal to America to rise to the call "to give a new translation of the ancient and ever new demand for the union of Liberty and Order" (p. 85). Two points need emphasis. First, "democracy perishes if it compromises with totalitarianism . . . whereas some socialism *must* be mixed with capitalism if capitalism is to survive" (p. 78). Socialism does not mean democracy (that is the "fallacy of the left") but capitalism does not mean democracy either (that is the "fallacy of the right"). Second, racial and ethnic discrimination is a "rank betrayal of our democratic faith" (p. 82) which "lowers our standing before the world" and "hurts us at home" (p. 83). "We must abolish discrimination. Only so can we fulfill the meaning of America. Only so can our great tradition become anew a vital reality" (p. 84).

University of Toronto

Economic Systems in Action: The United States, the Soviet Union, and the United Kingdom. By ALFRED R. OXENFELDT. (New York: Rinehart. 1952. Pp. ix, 175. $1.50.)

The purpose of this book, the author tells us, is to achieve two goals. His plan was to write a brief and nontechnical text that could be understood by an "intelligent high school graduate." The material presented was to be "organized around the basic functions that every economic system is expected to perform." It is the impression of the reviewer that the pedagogical aim has been fully realized. The book is admirably suited for beginners in economics, either as a supplement to the principles text or for a class in current economic issues. It is hardly a satisfactory text for a systematic course in comparative economic systems, mainly for its theoretical particularity.

The central proposition of the author is that to compare is to evaluate. Evaluation requires standards of judgment as well as identical problems to be solved by each economic system. Each economy has to solve five identical questions: what and how much to produce, how to divide income adequately, how to select the most efficient methods of production, how to direct individuals into the most productive occupations, how to improve the progressiveness of the economy. To answer these questions, the author develops standards of performance appropriate for each system. The actual performance of the American economy is compared with the welfare standards of efficiency and equity. The Soviet economy is compared with the standard of a "good economic plan." British socialism is compared with the standard of full employment and income equality. What is the result?

A significant body of information is presented effectively in terms of standards and actual performances. Yet two deficiencies are obvious. In many cases the standards of judgment defied operational definition. Or the evidence necessary to measure the degree of attainment was missing. In the few instances where standards and data were adequate, the conclusion was that neither one of the economic systems considered was as effective as it could

or ought to have been. The best one can achieve with this method is to indicate deficiencies that can be remedied within the framework of each system. The method can tell us little about the degree of compatibility among these systems.

More serious is the fact that a comparison in terms of ideal standards does not allow for a discussion of essential institutions of the actual economies. For instance, the treatment of the American economy does not include a systematic discussion of the economic rôle of large corporations, trade unions, or farm organizations. The welfare standards chosen presuppose effective competition and did therefore not call for a discussion of how these three institutions have changed the actual functions performed by the pricing system. In assessing the achievement of the Soviet Union, the institution of forced labor is regarded as noneconomic, imprisoning merely the politically dangerous. The ideal standard of the highest possible output, which would be higher if free labor only were employed, is utilized to argue that forced labor is not in the interest of the Soviet Union (pp. 114-115), and must thus be insignificant.

Although the author has utilized his method with great skill, often going beyond its inherent limits, it seems to the reviewer that presentation of the essential institutions must precede evaluation if students are fully to understand the actual operation of contemporary economic systems.

ARTHUR SCHWEITZER

Indiana University

The Cooperative Movement and Some of Its Problems. By PAUL HUBERT CASSELMAN. (New York: Philosophical Library. 1952. Pp. xiii, 178. $3.00.)

The author of this well-written little book is a professor of economics at the University of Ottawa who has been active in the cooperative movement. The Foreword is by Dr. M. M. Coady, a leader of the Antigonish Movement. As the author points out, apart from James P. Warbasse's *Cooperative Democracy*, and Horace M. Kallen's *The Decline and Rise of the Consumer*, few major works in America have dealt with the cooperative movement's basic problems. That is the main purpose of his book. Hence it is addressed primarily to those familiar with cooperation (Introd., p. xi). Professor Casselman's approach is not doctrinaire. Cooperation is not held up as a panacea for all economic and social ills. On the contrary, recognizing that this method is not always superior in every line of endeavor, he doubts the feasibility of a cooperative commonwealth, and favors instead the competitive yardstick goal of using cooperatives to curb the evils of capitalism (pp. xii, 11, 52).

An introductory review is given in Chapter 1 of the working principles of cooperation, classified according to the ideals underlying them. The purpose of Chapter 2, which deals with attitudes toward and major schools of cooperation, is not clear. Is it merely descriptive, or is it intended to show that indifferent, neutral, and hostile groups constitute one basic problem, and lack of agreement among cooperators constitutes another?

Chapters 3-9 come to grips with the main problems of the cooperative

movement. In considering problems of cooperative organization, Casselman rightly stresses the primary need for organizing financial cooperatives of various types. Concerning the problem of effective education, useful suggestions are made in accord with principles of progressive education, and the Antigonish Movement, which uses cooperation as an instrument of education, is described. Of the two chapters devoted to a comprehensive analysis of the cooperative movement's relation to the state, one gives detailed attention to its relation with socialism. Here perhaps Casselman could have devoted less space to proving a fairly obvious point—that "cooperatism" differs from socialism in certain fundamental ways. His discussion of cooperative-state relations would have benefited from J. P. Warbasse's *Cooperative Peace* (1950), which is nowhere mentioned. A valuable chapter is that dealing with cooperatives and labor. Subjects covered include the advantages of cooperatives to labor, participation by labor in the movement, labor's relative indifference in America compared to Europe, and sources of cooperative-labor friction. Discussion of producer-consumer relations among cooperatives is less complete, but interesting and informative. Finally, the problem of taxation is covered fully and competently. According to the author, patronage dividends paid out or retained by producer purchasing and consumer cooperatives are neither taxable as personal income nor as corporate income. These organizations are in no sense corporations, and moreover, patronage dividends consist of overcharges, or of withheld savings from group buying (pp. 140-42). By way of conclusion, Chapter 10 makes a final plea for cooperation, after reviewing its advantages.

The book is perhaps too brief, and at times lacks the depth of *Cooperative Democracy* and *The Decline and Rise of the Consumer*. It is, however, extremely readable and a welcome addition to the literature of this field. Valuable features are the careful documentation, a twelve-page bibliography by chapters, and an adequate index.

National Income and Social Accounting

Wages and Salaries in the United Kingdom, 1920-1938. By AGATHA L. CHAPMAN assisted by Rose Knight. Stud. in Nat. Income and Expenditure of the United Kingdom, No. 5. (Cambridge: The University Press. 1952. Pp. xiv, 242.)

Miss Chapman's study *Wages and Salaries of the United Kingdom, 1920-1938* is the most recent in the series on national income and expenditure which the University of Cambridge and the National Institute of Economic and Social Research are issuing. The study is a work of admirable and indefatigable scholarship. This is fortunate not alone for those concerned with employment and wages in the United Kingdom. It is equally fortunate for those econometricians and business-cycle analysts who would use UK data for

national income and expenditure to study growth trends, savings-income ratios, etc.: with wages constituting two-thirds of national income in this period the accuracy with which they are estimated will substantially affect the accuracy with which national income as a whole will be estimated.

Aside from an introductory chapter on definitions and concepts, and two others on the reliability of the estimates, Miss Chapman devotes the entire study to describing how she prepared the annual estimates for employment, wages and salaries and average annual earnings (*i.e.*, full-time equivalent). To assess the study adequately would demand considerable time—to work through 200-odd pages of patient investigation—and a broad acquaintance with the intricacies of British economic data in virtually every field. However, we may attempt a trans-Atlantic judgment on at least the verisimilitude of the final estimates in the light of American data trends and economic relationships.

For estimating employment, her general procedure is to use benchmarks from the Production Censuses of 1924, 1930 and 1935 (or the Population Censuses of 1921 and 1931) and interpolate by employment series derived from data of the unemployment insurance system. For wages and salaries, chief reliance is placed on E. C. Ramsbottom's indices for wages and the Marley-Campion indices for salaries. Given the nature of these raw materials, it is unlikely that substantial improvements in the accuracy of the estimates could be made. It is important, however, to surmise how adequate the estimates prove to be.

One critical aspect is how well they portray cyclical variability. Of the cyclical changes in her records, the most extreme—as in that for the United States—is the 1920-21 drop, and it is therefore worth special attention. From 1920 to 1921 rates of pay (as measured by average annual earnings) declined by 5 per cent (or less) in every industrial group but two—fishing and mining. For these two groups, rates declined about 20 per cent. Cash mining wages dropped by 100 million pounds—or far more than the drop during the 8-month strike year of 1926. The somewhat unlikely spread in earnings trends may be related to the methods of estimate. For mining, Miss Chapman uses a different procedure for the year 1920 than for subsequent years. She does not indicate how closely such a procedure reproduces benchmark data in later years—hence we do not know how comparable the 1920 and 1921 estimates may be. For fishing, the drop rests on the implicit assumption that wages form a constant ratio to value of fish landed. This assumption, Miss Chapman is careful to point out, does not fit well with data for years in which we can check it (1929-34, 1938). Moreover, it is likely that the employees' share was in fact smaller in the high 1920 prosperity than in later years.

Turning from the wage rate sources of the 1920-21 decline, what of the employment shifts? For manufacturing and a number of other major groups the 1920-1921 change is estimated as the change in the numbers of insured workers minus the number of insured unemployed workers. The latter group is defined to include persons on short-time. Since the number of short-time workers increases in depressions, that group will constitute a growing number of employed full-time equivalent workers. Miss Chapman's treatment of them as completely unemployed, therefore, is likely to overstate the 1920-21 decline.

For trade, finance, insurance and a substantial part of the service industry, it is arbitrarily assumed that employment declined by 10 per cent. Such a decline is modest in the light of declines in, say, manufacturing employment. However, its reasonableness is still in question: no decline occurred in any subsequent year between 1921 and 1938—neither in 1926, the year of the general strike, nor in the depression following 1929. Since, therefore, wages and salaries are estimated for 1920-21 as the product of employment times an average wage-salary, the combined effect of this treatment of short-time in many industries, and the assumption of decline in others, is likely to overstate the 1920-21 decline.

Miss Chapman's figures show an almost unvarying level of wages and salary aggregates from 1921 to 1933-34. Prosperity such as that of the American 1920's is completely absent in the British record. Manufacturing wages—one of the most sensitive earnings groups—are almost identical in 1924, 1930 and 1935—years for which benchmark Census of Production information is available. *A fortiori,* other industry groups show a similar stability over these years.

The 1932-38 change provides another point of interest for cycle analysis, reaching as it does from the lowest point in the depression to the last year for which this study provides figures. Here, too, the results are mixed. According to Miss Chapman's estimates, the average annual earnings of employees in manufacturing rose by 10 per cent over this period, with correspondingly smaller increases in distribution and service. However, the gain shown for agriculture is 18 per cent. In the United States economy such a disparity, and in this direction, would be unreasonable. This gain essentially represents the change in the minimum rates set under the Agricultural Wages (Regulation) Act in certain contested cases. As such, it is not likely to allow for changes in the percentage of persons working at minimum rates and the percentage working above these rates. In a recovery period, such as 1932-38, it is likely that these proportions—and hence average earnings—would shift differently from a set minimum rate.

Miss Chapman cannot be commended too much for her care in comparing her results with those of Bowley, Clark and a multitude of other official and nonofficial check points. Some of the comparisons reveal a consistency in British data which is far greater than we could hope for in similar American sources: for example, the number of national and of local government employees as reported in the 1931 Census of Population is almost identical with the totals reported by the individual departments and organizations. On the other hand, some of the comparisons prove a bit misleading. For example, the earnings bill as estimated in this study for trade in 1924 is compared with an estimate based on a special earnings inquiry of the Ministry of Labour in that year. The virtual identity of the two estimates, however, essentially rests on the fact that the wage totals are secured by multiplying identical employment figures first by the rates of earnings in certain distribution trades and second by rates for cartage and haulage and for warehousing and cold storage, and these rates were almost identical.

A terminal chapter on reliability of estimates follows the tradition of King

and, more immediately, Kuznets in trying to assess for the reader the reliability of the results for the years 1920 and 1938. This is further testimony to the scholarly nature of the study but it is doubtful whether this tradition is worth perpetuating. To say that the figure for average annual earnings for agriculture in 1938 is Class B (a firm estimate) is a judgment we must respect. But it is equally a judgment which may be contested: no benchmark estimate exists to fix a level for this series, and—more importantly—most users are concerned with the still more difficult question of change.

In future editions it would be informative to have a chapter comparing employment and output trends, with some commentary on the implied productivity measures, and some comparisons between the trend in wages and salaries on the one hand and the—presumably independent—Cambridge-N.I.E.S.R. estimates of consumer expenditure on the other hand. Economists are certain to be interested in the labor market relationships revealed by these figures—with changes in employment being positively correlated with changes in wage rates in some industries, negatively in others. Perhaps Miss Chapman herself will report on these in some future analysis.

It is to be hoped that the ability, care and hard work which are apparent in this review of wages and employment in the United Kingdom—gaps filled, sources reconciled, estimates patched up—will be equally apparent in future studies in this series. The results of Miss Chapman's work are certain to be used widely and frequently in the years to come.

STANLEY LEBERGOTT

Washington, D.C.

Business Fluctuations; Prices

Federal Grants and the Business Cycle. By JAMES A. MAXWELL. (New York: National Bureau of Economic Research. 1952. Pp. xiii, 122. $2.00.)

Several "built-in stabilizers" have been added to the public sector of the economy during the past two decades. Expenditures have been made more responsive to cyclical swings in business activity through the adoption of the unemployment insurance program and the system of price supports for agricultural products. Revenues have also been made more responsive, largely as a result of the increased relative importance of income and profits taxes. The mildness of the 1949 business decline and the speed of the subsequent recovery can doubtless be attributed in part to the operation of these automatically compensatory fiscal adjustments.

Stabilizers of this type have obvious appeal. The existing devices, however, need considerable strengthening before they can be important in cushioning a large-scale business depression. How might this strengthening be accomplished? This book examines a particularly promising avenue of approach, namely, the possibility of establishing flexible federal grant programs which would serve a countercyclical purpose and also place certain governmental

services on a more assured basis in both prosperity and depression. The author's conclusion—stated more implicitly than explicitly—is that a feasible plan can be worked out which would achieve an important countercyclical effect.

There is far more in this small volume than appears at first glance. Professor Maxwell has given us a very compact and useful description and analysis of the important federal grant programs: their history, their size, their behavior during business cycles, the lessons of experience, the defects in the programs, and the proposals for reform. He also presents a careful and concise analysis of public works, both federal and state-local. But this is not all, for the author breaks new ground by introducing some original and highly attractive proposals for automatically compensatory grant programs. The book follows the typical pattern of National Bureau publications: controversial issues are treated very cautiously, generalizations are few and guarded, there is a minimum of literary flourishes, and as much as one-third of the volume is devoted to statistical tables and charts. However, Maxwell has been more successful than most writers for the National Bureau in providing a stimulating treatment which molds statistical and theoretical conclusions into practical proposals for governmental action. These proposals are all the more worthy of serious consideration because of the author's long experience in the field of intergovernmental fiscal relations and the campaign he has waged to make students of public finance more appreciative of the significance of federalism.

One cannot help being greatly impressed with the ingenuity behind the author's proposal for a flexible scheme of public assistance grants covering public assistance as a whole or selected categories of assistance. In brief, the scheme involves the establishment of a national minimum expenditure per recipient, the computation for each state of a "standard effort," which represents the potential state expenditure per recipient if a given percentage of state income payments is devoted to this purpose, and the determination of matching ratios based upon the relationship between the standard effort for a state and the national minimum.[1] The federal government's share would be the largest for the poorest states, and the smallest or nonexistent for the wealthiest ones. This scheme is flexible, since both the national minimum and the standard effort can be changed. It is automatically responsive to the business cycle, because a given percentage state-local standard effort would cover more of the national minimum in periods of high income than in a depression, and because the federal share of the cost of the program would grow and shrink directly with the number of persons who became eligible for benefit payments. Maxwell is aware that the operation of a plan of this sort would face certain dangers and difficulties, and he suggests how these might be kept to a minimum.

The proposal for public works involves the creation of a federal public

[1] This scheme is an extension of the author's earlier thinking on this subject. (See J. A. Maxwell, *The Fiscal Impact of Federalism in the United States* [Harvard University Press, 1946], Ch. 17).

works authority which would program federal projects according to cyclical conditions and exert cyclical control over state-local construction expenditures. The latter control would operate through grants for planning public works and through cyclically variable grants and loans for financing projects that have already been planned and cleared in advance. The author takes cognizance of the important obstacles to the use of public works spending for damping business fluctuations. Various factors which influence the timing of public works are analyzed, such as the limits to the deferability of projects, the complementary nature of certain types of public and private construction, and the long period often required for planning and construction. Evidence is presented showing that governmental agencies responsible for construction projects often like to see their projects initiated and completed as rapidly as possible and tend to be reluctant to fit their operations into a countercyclical pattern.

A minor objection might be raised to Maxwell's suggestion that the level of private construction be used as the chief guide to policy decisions concerning the timing of public works. Private construction does not always move with the general business cycle (witness 1927-29) and, therefore, will not always be a reliable guide. Some critics might deplore the fact that the different grant and public works proposals are not developed within a broader fiscal policy setting which allowed for other types of expenditure flexibility and for tax adjustments, but an extended treatment of that type is clearly beyond the author's assignment.

This volume is the fifth publication of the National Bureau's Conference on Research in Fiscal Policy. The fact that it includes a rather full discussion of policy questions is partly a reflection of the fact that the initial suggestion for the study came from the President's Council of Economic Advisers.

HASKELL P. WALD

Washington, D.C.

Business Cycles. By D. HAMBERG. (New York: Macmillan. 1951. Pp. ix, 621. $5.00.)

There are now a half dozen textbooks in the field of business cycles, and there are few fields of economics in which the texts are so uniformly good. Professor Hamberg's book is no exception. It is fully up to the high standard set by its predecessors, and possesses some distinctive features that will surely appeal to many teachers.

The book is divided into three parts. Part I consists of introductory material, beginning with a chapter on statistical aspects with an appendix in which the chief methods of time-series analysis are briefly sketched. The second chapter lays the theoretical basis for the subsequent discussion by introducing the concepts of national income and product, and proceeding to a preliminary treatment of income fluctuations. The final chapter in Part I develops the multiplier and accelerator, and their interaction in simple models.

Part II, "Theories of the Business Cycle," occupies roughly half the remainder of the book. The first of seven chapters, and the longest, deals with Keynes and the stagnation thesis in considerable detail. Further chapters

cover the pure monetary theory with particular reference to Hawtrey; the monetary and nonmonetary overinvestment theories, with a seven-page appendix on the Ricardo effect; Schumpeter's theory; "Underconsumption Theories," treating the work of Foster and Catchings and Hobson as representative. There is a chapter on agriculture, cost-price relationships, and expectations, under the title, "Influence of Strategic Factors"; and another concerned with international aspects of cyclical fluctuations.

Part III opens with a chapter on "Eclectic Theory of the Business Cycle," in which exogenous and endogenous forces are distinguished, and a synthesis of elements of the theories previously discussed is developed. Further chapters provide historical accounts of business cycle history in the United States in the 'twenties, 'thirties and 'forties, respectively. Two others deal with monetary policy and fiscal policy.

As his distribution of space would suggest, Hamberg believes that an undergraduate course in business cycles should emphasize theory rather than either history or policy. He believes, moreover, that there are substantial advantages to be derived from a translation of the various terms used by different writers into a common language, and he has employed a "Keynesian" vocabulary throughout the book. Thus, the Wicksellian "natural rate of interest" is rendered as "the marginal efficiency of capital," and so on. This device is skillfully and consistently applied, and will certainly save students a great deal of drudgery as well as some confusion. Whether this is a merit or a defect of the book is, of course, an arguable question. Hamberg has not tried to please everyone, but he has made what many will regard as a considerable contribution to effective teaching.

Hamberg's book is much too good to appeal to the charitable instincts of a reviewer. The author has exercised his obvious competence with a strict view to the capacities of his undergraduate audience, and he has taken pains to work out an interesting and comprehensible presentation of his subject matter. Although his chief concern is admittedly with theory, he has not slighted his chapters on history and policy, and his style is adapted to the narrative in a manner calculated to keep readers awake. On controversial questions, the author states his own position and labels it as such, thus opening the way to further discussion. Any instructor can use this textbook as the basis for a high-level course in business cycles, and whether or not he chooses to do so is largely a matter of taste in the competitive scene. Disciples of the late Professor Mitchell will feel that he gets short shrift in the page and a half given him, and those teachers who have no use for the aggregative approach will naturally prefer another product. Given Hamberg's objectives, however, there is little fault to be found with his book. The flaws to which I now call attention stand out as minor deficiencies in an excellent piece of work.

Chapter 2, after giving a very clear statement of the definitions to be used throughout the subsequent analysis, proceeds immediately to a treatment of income fluctuations in which the distinctions just made are ignored. If the student has heeded the author's warning to familiarize himself thoroughly with the concepts, "particularly saving and investment," he will be disconcerted by an analysis that seems to make changes in the level of *national* in-

come depend upon the relation of investment to saving out of *disposable personal* income. Furthermore, the statement on page 50 that "whenever reference is made to consumption in relation to income, we will ordinarily be referring to disposable income," is not borne out by what follows. The propensities to consume and to save are actually discussed in terms of *national* income, and the illustrative tables and graphs in both Chapters 2 and 3 show national income as the independent variable. Since the terms "national income," "received income," and simply "income" are all used interchangeably in both these chapters, students will need some help if they are to understand just what is going on. I suspect that an explanatory paragraph or two was left out of the final version of the manuscript somewhere in the second chapter.

In the chapter given to Schumpeter's work, the aggregative terminology does not show at its best, but the exposition is nevertheless adequate to give students a sound introduction to a subject of increasing interest. It is thus especially disappointing to discover among the "Critical Remarks" with which this chapter, like the other theoretical chapters, concludes, some erroneous comments of a most misleading character. Hamberg's minor criticisms of Schumpeter are possibly debatable, but on the major points he is quite wrong. Schumpeter never held that the distribution of entrepreneurial ability is anything other than "rather gradual" (see Schumpeter's *Business Cycles,* Vol. I, pp. 99, 130, for instance); and there is no "Great Man Theory" of history to be found anywhere in his work (compare *Essays of J. A. Schumpeter,* pp. 216-35, and especially p. 234, n. 10). Hamberg will undoubtedly make good these lapses at the first opportunity; meanwhile, they may be used as a basis for some profitable class discussions.

RICHARD V. CLEMENCE

Wellesley College

Money and Banking; Short-Term Credit; Consumer Finance

Federal Reserve Policy-Making. By G. L. BACH. (New York: Alfred A. Knopf. 1950. Pp. xvii, 282. $3.00; text ed., $2.20.)

Students and teachers of money and banking who are constantly looking for more and improved material for monetary courses above the elementary level will be intrigued by this volume by Professor Bach.

The book has two main purposes: (1) A study of the *process* of Federal Reserve monetary and bank-supervisory policy formation, and (2) a look analytically at the policy-making experience of the past quarter century to see what lessons it may have for the future. The study does not deal with monetary theory or an evaluation of monetary policies. Emphasis is upon whether present organization and procedures have assisted in the formation of "good" policies. It is partly a product of research done by Bach for the Hoover Commission in 1948.

Part I relates to Federal Reserve organization and responsibilities. For

those acquainted with the field of money and banking, this section covers material with which the reader will have had frequent previous contact in most texts and in Federal Reserve System publications.

Part II deals with internal policy formation, giving attention to open market operations, reserve requirements, discount rates, selective controls, bank supervision, direct lending and a discussion of those who make Federal Reserve policy. This section also has much in it which informed students of American banking already know. However, it is seasoned with significant observations on the human aspect of Federal Reserve operations and the degree to which the personnel of the Board, Open Market Committee and of other groups play upon the policies which are made. This aspect of the volume makes it somewhat unique among recent studies of the Federal Reserve. It could only be written by someone like Bach who has had personal contacts as a member of the Federal Reserve staff and other governmental agencies. Numerous critical observations are made, such as on page 59, where it is remarked that a body of 25 to 30 people, as usually make up the Open Market Committee meetings "has not been found a highly effective deliberative body."

Part III analyzes the external relations of the Board and their impact upon policy-making. These include the Treasury, Securities and Exchange Commission, the Executive Office of the President, and bank supervisory agencies such as Federal Deposit Insurance Corporation, the Comptroller of the Currency and the State bank examination departments. A discussion of Treasury leadership in monetary-fiscal matters and the independence of the Board (Ch. 11) is of great current interest in the light of the Douglas and the more recent Patman Subcommittee reports. Unfortunately this book was written before the accord between the Federal Reserve and the Treasury. The current scene has somewhat changed and monetary policy has regained some lost ground since Bach wrote. After reading the volume, one should read the Hearings before the Patman Subcommittee[1] including Bach's panel discussion (pp. 748-61).

Part IV analyzes the meaning of much that was discussed in the earlier portion of the book, and for many will be the section which makes the greatest contribution. Whether one agrees with the author on all points is of less significance than that stimulation is provided to consider many phases of the organizational-policy-making procedures of our central banking system, an area so frequently neglected. From statements such as, "Control of the nation's money supply is one of the most basic powers a government can and must have (p. 234)," with which most everyone will agree to, "There is a serious question whether bank examination in this country during the past quarter century has done more good than harm" (p. 245), with which many will disagree, there is plenty to stimulate thought. For example, it is suggested that the Federal Reserve either should have greater independence from the Treasury if a central bank is to be maintained, or the central bank should be brought closer to the Treasury. As now constituted, the advantages of neither

[1] *Monetary Policy and the Management of the Public Debt; Hearings Before the Subcommittee on General Credit Control and Debt Management; Eighty-Second Congress* (Washington, 1952).

are secured (Ch. 13). The author leans toward a more independent Federal Reserve with a greater responsibility to participate in government policy formation. However, the drastic suggestion that the Treasury might borrow "only or largely from the Federal Reserve" and the Federal Reserve would have the power to issue and deal in its own securities (pp. 219-20), should at least lead to lively discussion among advanced students.

A reviewer should not quarrel with a writer who competently does what he set out to do. However, it is unfortunate that as much space was taken for the material which is generally known in the professional field when greater analysis of the part to be played by monetary and fiscal policy is needed. Perhaps Bach will provide us with this in a subsequent study.

Federal Reserve Policy-Making is well written. It can be a vehicle for stimulating group discussion and is recommended for use in monetary courses beyond the elementary level. The emphasis on the impact of organizational and personnel factors upon policy is a useful and needed contribution.

FLOYD R. SIMPSON
Los Angeles State College of Applied Arts and Sciences

Geld und Kredit. By ALBRECHT FORSTMANN. 2 vols. (Goettingen: Vanderhoeck & Ruprecht. 1952. Pp. 821. DM 53.50)

In his treatise on "Money and Credit" Albrecht Forstmann (according to the publisher, Germany's leading monetary theorist), has made an important contribution to economic literature. His two-volume work, which covers all the problems of monetary theory and monetary policy (excluding the rôle of money in international relations), is an excellent introduction to this field of economics. The book contains an integrated reinterpretation of the views of most of the prominent German and non-German writers and some original ideas of the author himself. The book is well organized, the exposition is systematic, and the information is, on the whole, up-to-date.

Although the author expresses his own views forcefully, he does not develop a specific theoretical system for which he could claim original and independent authorship. His comments and conclusions are interspersed in the text, and it is difficult to disentangle them from the opinions of those writers (or their critics) whose theories are discussed and analyzed by the author in detail.

Forstmann's eclectic approach to monetary theory is reflected in his method of presentation. He proceeds step by step, quoting extensively from the writings of other economists on each subject, and indicating his approval or disapproval of their opinions. Points of disagreement between different theories and policy objectives are clarified wherever necessary. This method of presentation adds historical perspective to the book. The book will be particularly helpful to students of economics who need both elementary and advanced instruction; and it is well suited for "practical" people, engaged in central banking, commercial banking, or public financial administration, whose understanding of theoretical problems will be enhanced by the thorough coverage of the existing literature in this field.

Precise language in the text is supported by the use of relatively simple algebraic equations, and occasionally by the use of diagrams. Effort is made to clarify the terminology of the subject by accurate definitions, and to facilitate the understanding of complex theoretical problems by elaborate classifications and sub-classifications. These efforts are, on the whole, praiseworthy; but the author's excessive preoccupation with detail and the deliberate use of repetition as a didactic device make the book ponderous.

In a short review the wide range of problems discussed by the author and the wealth of material presented in the text can hardly be summarized. It is impossible to duplicate here the exposition of the ideas of many writers whose contributions to the text—both in volume and in substance—far exceed the author's own contribution to monetary theory. The following remarks are, therefore, largely confined to a quick survey of the organization and contents of the book.

The author may be described as an opponent of the "New Economics" in the strict sense of the term. However, his sharp criticism of elements of the Keynesian theory does not prevent him from accepting, by and large, the Keynesian approach and many Keynesian conclusions. Keynes is more frequently and more extensively quoted in the text than any other writer (most quotations, however, are from Keynes' *Treatise on Money*, not from the *General Theory*). Apart from Keynesian ideas, the influence of Wicksellian thought appears to be predominant. Wicksell's theory of the cumulative process (with some modifications) occupies a central position in the book. Altogether, quotations from more than seven hundred writers are incorporated in the text; among them are Eucken, Haberler, Hahn, Hayek, Myrdal and Schumpeter, who are more extensively quoted than others. This indicates not only a preference for books written in, or translated into, the German language, but also a preference for certain theories.

The book is divided into two volumes, roughly corresponding to the division of the subject into "pure" and "applied" theory. The first chapter of Volume I contains an outline of the scope of the analysis. Forstmann's aim is the integration of monetary theory with general economic theory. He sets himself the task of exploring all the factors which determine the influence of monetary phenomena on real economic processes.

Chapters 2 and 3 contain a comprehensive discussion of the basic elements and principles of the theory of money, credit, and capital. In this section (pp. 28-124) the author describes the various kinds of money, and the functions of money, in great detail, before he turns to the analysis of the various theories of value of money (pp. 125-208). The form of presentation of these theories is characteristically didactic procedure. They are divided into three groups: (1) value theories (subdivided into subjective and objective theories); (2) price theories (production cost and quantity theories); and (3) income theories (static and dynamic). The quantity theory (in any form) is rejected on various grounds (because it deals with symptoms rather than determinant factors, because it ignores changes in relative prices, etc.). None of the arguments used are particularly original, but they have been given a "new look." The author then criticizes Keynes' "static" income theory (from the

"Treatise"), and finally proceeds with the discussion of the dynamic income theory to which he subscribes (pp. 193-208). The author does not attempt to demonstrate here or in any other part of the book that the theories presented are capable of statistical application.

In the chapter on the theory of credit (pp. 209-98) the author discusses the interrelationship between money, credit, and capital, including the functions of the interest rate. The dichotomy between the theory of money and the theory of credit is for the author more than a matter of terminology. He emphasizes the point that real economic processes are affected primarily by changes in the "circulation of credit" (*Geschaeftskreislauf*). Changes in the credit volume are only later reflected in the "circulation of money" (*Einkommenskreislauf*). The problems of credit creation (by the banks) are discussed in great detail, especially those related to the extension of credit in excess of the supply of savings (*"zusaetzlicher" Kredit*). Such "additional" credit expansion (which is in most cases used for the acquisition of real capital) is, according to the author, one of the most important disequilibrating factors, because it tends to increase the money supply without a corresponding increase in the supply of consumers' goods; thus a new equilibrium can be reached only at a higher price level (unless this tendency is compensated by other equilibrating factors).

The second volume of the book deals with the application of monetary theory to a great variety of economic problems. In the fourth chapter (pp. 307-522), which is based mainly on Wicksellian and Keynesian ideas, the central thesis of the book is developed. The factors determining the "neutrality" or "non-neutrality" of money are analyzed in detail, largely in terms of the Wicksellian divergence between the market rate and the "natural" rate of interest. The greater part of the discussion, however, is devoted to a critical restatement of the modern theories of saving and investment, income and employment. Emphasis is placed (in contrast to Keynes) on the problems of hoarding and dishoarding, and changes in inventories. The problems of "forced" saving and misdirection of investment are fully analyzed; the theories of the multiplier and the acceleration principle are discussed (with approval), and the liquidity preference theory of interest is criticized and rejected. This chapter also includes a general discussion of business cycle theories which involves much repetition of earlier arguments.

In the short fifth chapter (pp. 523-91) the author is concerned with purely institutional problems. He discusses in theoretical terms the limitations of the functions of money and credit in different types of economic systems, *viz.*, a free market economy, a "regulated" economy, and a totally planned and centrally administered economy.

In the sixth chapter (pp. 592-745) the instruments and principles of monetary and credit policy are described and analyzed. In the discussion of policy objectives the author favors an active monetary policy directed toward the full utilization of resources. He expresses his preference for a managed monetary standard aiming at the stabilization of the wage level (index of average nominal wages) or the stabilization of a weighted price average in which wages are included.

An excellent bibliography and index complete the text.

It is surprising to find in a recent book by a German monetary expert practically no reference to postwar monetary developments in Germany. The currency reform of 1948 is not even mentioned.

The fact that the author regards the rôle of money in international relations as a matter which lies outside the scope of his investigation is regrettable. It is one of the shortcomings of an otherwise comprehensive survey of the problems of monetary theory and monetary policy.

Corporate Income Retention, 1915-43. By SERGEI P. DOBROVOLSKY. (New York: National Bureau of Economic Research. 1951. Pp. xviii, 122. $2.50.)

This book is the most recent of the studies in Business Finance under the Financial Research Program of the National Bureau. The object of the study (p. 1) is "to ascertain whether corporate income retention has followed stable patterns during the years analyzed." More specifically, the author analyzes the extent to which variations in income retention have been associated with changes in corporate profitability and how closely these variations are related to changes in corporate investment.

After defining his terminology, Dr. Dobrovolsky begins his study by presenting charts and data on the net income, dividends, and retained income of all manufacturing corporations (based on U. S. Treasury Department, *Statistics of Income, 1922-43*), and similar information on a sample of 45 large companies, and 73 small and medium-sized manufacturing companies for slightly longer periods. In analyzing these time series, attention is directed to the proportion retained at various levels of corporate net income, how changes in net income from one year to the next were reflected in retentions and dividends, the trends in corporate retentions, and the extent to which income retentions were affected by factors other than profitability. The author finds that net income retention usually began when corporations were earning in excess of 5 per cent of net worth. Below that level dividends were paid in excess of current income. In examining annual changes in net income and retained income a fairly stable relationship appeared. On an average, corporations tended to disburse or contract dividends to the extent of about 20 to 30 cents for each increase or decrease of $1 of net income (per $100 of net worth). In other words, while the corporate propensity to save varied with the level of income, the marginal propensity to save remained fairly stable above a certain level of net income.

* The views expressed are those of the reviewer and do not necessarily represent those of the organization with which he is connected.

After this analysis of aggregates of companies, the patterns of relationship between income, savings, external financing, and physical asset investment of individual companies in single years and in longer periods are examined. Differences between companies also are considered. In this phase of the study Treasury data on all mining and manufacturing companies are used, as well as the samples of large, and of small and medium-sized companies. In periods of heavy investment, both internal and external financing tend to be absorbed. In periods of cyclical contraction there tends to be a disinvestment in physical assets, dissaving, and a release of external financing on balance. However, the pattern is less distinct for the samples of large and of small and medium-sized companies. In the concluding chapter, the relations between the rates of physical asset expansion and retained income are examined. It is interesting that even when the rate of expansion was highest during the period studied, the absolute amount of retained income exceeded the net amount of external financing absorbed. The findings of the study are summarized in the first chapter.

This carefully prepared and well-documented study provides more complete factual information on an important controversial area than has previously been available. The findings will be of greater interest to general economists than to students of corporation finance. The reader found that the study in large part confirmed assumptions that he had made rather than being a source of new ideas, but a statistical study of this type is valuable in providing concrete information where such has been lacking. It should be borne in mind that the data pertain largely to the manufacturing sector of the corporate economy, and that such important areas as the railroads and the utilities are not covered.

Effects of Taxation: Corporate Financial Policy. By Dan Throop Smith. (Boston: Grad. School of Bus. Admin., Harvard University. 1952. Pp. xii, 301. $3.75.)

Effects of Taxation: Depreciation Adjustments for Price Changes. By E. Cary Brown. (Boston: Grad. School of Bus. Admin., Harvard University. 1952. Pp. xiii, 161. $3.25.)

These two books constitute the fifth and sixth volumes in the study of the effects of taxation upon business sponsored by the Harvard Graduate School of Business Administration. As is typical of the series, the studies are not expected to advance positive conclusions based upon substantial empirical work of actual effects of taxation upon business, but to explore the problems by careful analysis developed in light of a background of empirical information.

The Smith study considers the effects of federal income taxes upon the choice of methods of corporate financing. Smith emphasizes the need for

considering the effects of taxation in their proper perspective, and devotes much space to the entire complex of forces conditioning the effects of taxes on financial policy in order to obtain this result. Primarily the study is analytical: the author attempts to explain what businessmen can be expected to do in response to the effects of taxes upon their cost-profit situations. But substantial empirical work was done as well; 175 men active in the business and financial community were interviewed to determine their actual reactions in respect to the tax. The results are not formally tabulated and presented separately, but are used as a basis for appraising the conclusions reached by the analytical approach, and particularly in determining the significance of tax factors in business decisions. The author does not seek to give a quantitative appraisal of the effects of the taxes, and offers few categorical conclusions; one important implication of the entire analysis is the realization that so many complicating influences affect corporate financial policy that simplified conclusions about tax effects cannot be made.

Separate treatment is provided for widely held and closely controlled corporations, with emphasis on the difference in behavior in the two cases. With the former, analysis is made of the effects of corporate income taxes upon the relative merits of debt, preferred stock, and common stock financing. Smith emphasizes the fact that the tax is neutral so far as debt financing is concerned; it does not actually reduce the cost of borrowing unless the money is used in such a manner that no increase in gross earnings is expected. The tax makes necessary a higher rate of return to cover preferred stock dividends and thus discourages this method of financing. So far as common stock is concerned, the problem is more complicated, and the author devotes substantial attention to the question of the nature of the cost which results from the sale of additional common stock. He reaches the conclusion that the dilution of prospective earnings per share is the most significant measure of cost. If stock sells below its asset value, dilution is almost inevitable if additional stock is sold. The corporate income tax, by reducing the price of the stock, will increase the cost of new stock issues and thus discourage them.

On the other hand, the corporate tax, while lessening funds available for expansion, does not make expansion from retained earnings more costly. The entire income tax structure encourages retention if stockholders as a group wish to save their earnings.

With closely held corporations the issues are somewhat different. The over-all income tax structure, with favorable treatment of capital gains, encourages wealthy persons to take over existing closely held corporations, and overcomes in part the factors discouraging investments in smaller concerns. The tax structure also encourages creation of complex capital structures, particularly to allow retirement of senior securities from earnings. The strong incentive given by the tax structure for the retention of earnings is noted, as well as the efforts made by law to check excessive retention. In a final chapter the tax obstacles in the way of withdrawal of part interest from a small corporation are noted.

The author avoids policy recommendations, except in respect to the treat-

ment of partial withdrawal of interest, and the suggestion for more liberal treatment of capital losses as a means of encouraging the preservation of small businesses.

On the whole, the volume represents a useful addition to the literature. The reader may be disappointed at the somewhat meager results of the empirical work and the lack of quantitative appraisals of the effects of the tax structure on such questions as debt-financing. But the complicated nature of the problem has limited contributions along these lines. Perhaps the chief deficiency in the whole analysis, and one recognized by Smith, is the lack of knowledge of the extent to which the corporate income tax is shifted. The analysis is based upon the assumption—explicitly stated—that shifting does not occur; to the extent that it does, many of the conclusions are not applicable. Much more study of the incidence of the corporation income tax is urgently needed. The author also does not attempt to develop the related question of the significance of the tax structure and government expenditures for the general interest rate level; modifications in the latter would alter some of the conclusions reached.

The Brown volume deals with the tax aspects of a problem which has been brought into prominence in recent years by inflationary trends—that of the significance for measurement of depreciation and business profits of the gap which has arisen between original cost and replacement cost of capital assets. In inflationary periods depreciation charges based upon original cost do not supply sufficient funds to maintain intact the real capital assets of the firm; thus in a sense current profits are overstated. Essentially the present tax treatment includes in current income the increased value of existing capital assets produced by price increases. The question is closely related to that of inventory accounting, which has received much more attention in the literature, and was analysed in detail from a tax standpoint in an earlier volume in the Harvard series.[1] Brown's study, facilitated by his extensive background in both accounting and economics, is the first thorough analysis of the depreciation question from a tax standpoint.

The early chapters are devoted to a discussion of the significance of price changes for business firms, a survey of business practice in experimenting with replacement cost depreciation for nontax purposes, and an estimate of the annual magnitude of the gap between original and replacement cost depreciation. The author's estimate is a figure of from $2 billion to $2-1/2 billion in the postwar years. Only limited empirical study of actual use of replacement cost accounting was possible, since experiments were discouraged by accountants and government agencies.

Chapter 4 contains an evaluation in terms of equity and economic effects of a shift to replacement cost for tax purposes. Brown regards a complete change in the concept of taxable income from monetary income to real income, if administratively feasible, as one which would increase the theoretical equity of the tax structure. But he regards the allowance of replacement cost depreciation, in the absence of such a general change, as undesirable from an

[1] J. K. Butters, *Effects of Taxation on Inventory Accounting and Policies* (Boston, 1949).

equity standpoint, since it would discriminate against the holders of financial assets compared to the holders of depreciable assets.

So far as economic effects are concerned, it is concluded that the use of replacement cost depreciation for tax purposes would be a destabilizing influence, whereas its use for corporate reports and policy purposes would be a stabilizing influence. Brown regards the former influence as the more significant one. From the standpoint of long-run effects in an inflationary period, the replacement cost basis would increase the level of capital formation, but this result is not necessarily advantageous.

The latter portion of the book is devoted to a survey of the various alternative methods of adjusting depreciation accounts for capital-asset price changes, and of the question of the appropriate index for making the changes. A basic conflict is encountered, in respect to both these questions, between procedures which are theoretically logical and those which are administratively feasible. At best the result can be only an uneasy compromise. In regard to methods the problem of variations in the extent of regularity of replacement is a serious complicating factor. In the selection of an index, the diversity in variation of prices of various types of capital assets and the fact that quality of capital goods increases over the years pose almost insuperable problems, if any high degree of accuracy is considered essential.

In conclusion, Brown favors the continuation of the original cost basis, primarily because it results in less inequity for the holders of financial assets as compared to the holders of capital assets, and partly because of the problems in the establishment of a suitable method of adjustment and a usable index. While some persons will question these conclusions through a different weighting of conflicting considerations, Brown's study demonstrates clearly that there is no simple solution to the problem, and that the obstacles to a more satisfactory treatment are very substantial. The book is a very worthwhile addition to tax literature.

University of Illinois

Effects of Taxation on Industrial Location. By Joe Summers Floyd, Jr. (Chapel Hill: University of North Carolina Press. 1952. Pp. ix, 155. $3.00.)

The basic purpose of this brief volume seems to be to ascertain tax differentials among specified cities in nineteen states and specified rural sites in thirteen states. The method assumes that identical, particularly described textile, furniture, and tobacco manufacturing plants are alternatively located at each of several sites (there is an assumption of city-rural sites in the instance of the tobacco plant). Then the author computes the general tax liabilities under local legal and administrative conditions for purposes of comparison. In general the taxes examined appear to include the state income, franchise, and state and local property taxes. The author seems to exclude such taxes as gross receipts licenses of Virginia cities, flat-rate licenses of Alabama

cities, and income taxes of Ohio cities. He appears also to omit all state excises imposed under general sales tax laws on lubricants and in the form of gasoline taxes on liquid fuel used incident to manufacturing, public utility taxes collected from producers and remitted to the state, and other miscellaneous revenue measures.

The data presented enable the author to estimate the general tax bill for a selected year and the differentials among the obligations which the manufacturing corporations described would have to meet at the several sites. The evidence indicates that the amounts due would vary widely from state to state and even from site to site within individual states. The difference between the lowest and the highest tax bill would amount to 2 per cent of the hosiery manufacturing corporation sales and 3.4 per cent of the furniture corporation sales. The differential among the computed tax bills in the case of the tobacco manufacturing corporation would be less than 1 per cent of sales. The intrastate differentials of the hosiery corporation range from 0.02 per cent of sales in the Kentucky rural sites examined to 1.26 per cent in New Jersey urban sites. The study discloses some significant results with respect to the size of the tax bill in particular states. For example, it is apparent that the hosiery manufacturing tax loads as analyzed are substantially lower in Connecticut and Massachusetts than in Arkansas, Georgia, Mississippi, North Carolina, South Carolina, and Virginia, notwithstanding the widespread impression that textile manufacturers have moved from New England to these states to avoid high taxes. In viewing the relationships between taxes and industrial development, the author, like other students of kindred subject-matter, finds little evidence of correlation. Notwithstanding the lack of a definable relationship, the author expresses concern over the lack of uniform state and local revenue practices and develops suggestions for correction.

The study deals with tax differentials, but it does not show that they affect industrial location. Also, there are some unfortunate errors of detail as, for example, the misunderstanding (pp. 92 and 93) of the Kentucky property classification statutes. Although the incomplete coverage of manufacturers' taxes might seem unfortunate, the failure clearly to set out what is and what is not included is more objectionable.

Viewed as a whole, the book seems clearly to make a net contribution to the analysis of manufacturing taxation. The text is presented in an attractive, clear, and vigorous style. The suggestion that the study can be helpful to both public officials in policy determination and to industrialists in the selection of manufacturing sites certainly represents a modest viewpoint.

International Economics

Trade and Payments in Western Europe. By WILLIAM DIEBOLD, JR. (New York: Harper and Brothers, for the Council on Foreign Relations. 1952. Pp. xvii, 488. $5.00.)

This book is a well-documented analysis of the efforts toward economic cooperation among western European nations since the war. In three main parts, each roughly a third of the text, the author analyses (a) the development and operation of the European Payments Union and its antecedents; (b) the efforts to remove import quotas, reduce tariffs, and curb discriminatory practices of cartels and governments; and (c) the experience of Benelux and the proposals for other customs unions. This is the second in a three-volume series, sponsored by the Council on Foreign Relations, on economic problems of western Europe. The first was a study of the European Recovery Program, *The Economics of Freedom,* 1950, by Howard Ellis and the Council staff. The third volume, now in preparation by Diebold, will deal with attempts to unify certain industries, like the Schuman plan for steel and coal, and steps toward economic integration other than customs unions.

So far as I know, the present volume is the most comprehensive study available in English of European economic cooperation. It is a timely book on one of the big problems of our day. The approach is aptly put by the author: "This book is neither an exhortation to the Europeans to cooperate nor an apologia to the Americans on behalf of the Europeans, showing how hard it is to cooperate. It is simply an attempt to help understand the events of these four years." In his conclusions, the author is equally modest. After presenting fairly the pros and cons of each issue, he cautions repeatedly against sweeping generalizations. Concerning customs unions, he emphasizes both the trade-diverting and the trade-creating effects. In evaluating EPU, after detailed analysis of its operations, he finds the material results relatively small and raises serious doubts whether EPU alone means a measurable advance toward general convertibility of currencies.

The specialist in international trade, as well as the more general reader, will find this a rewarding book. For the former, in particular, there is an excellent critical bibliography of some thirty pages. The author is unusually generous in giving credit to others for even the smallest ideas.

J. RICHARD HUBER

University of Washington

International Cartels: Economic and Political Aspects. By KENNETH L. MAYALL. (Rutland, Vermont: Charles E. Tuttle Co. 1952. Pp. x, 173. $2.75.)

This report of research in the literature of cartels is notable chiefly for the positiveness of its conclusions. The author sets "objectiveness" as his goal, and undertakes to subordinate wishful thinking on the cartel question to "the plane of reality." The reality that emerges is familiar: international cartels are so ingrained in thinking and practice throughout the world that they

must be accepted as here to stay. A unilateral American policy of international trust-busting would be futile, and the substitution of governments for private participants would result in added dangers and no probable improvement in conduct. This position is quite defensible even though it is not the only position which the evidence can be made to support.

The author is unwilling, however, to permit this inevitable movement to run rampant without controls, and at this point his realism becomes somewhat diluted. He proposes: (1) registration of international private agreements, and the establishment under the United Nations of a technically competent legal tribunal to pass judgment on violations of international antitrust regulations; (2) guarantee of adequate consumer representation in all intergovernmental commodity control agreements; and (3) fair and impartial distribution of raw materials under control of a nonpolitical international economic council. These recommendations are likely to appear as decidedly less than "realistic" to anyone familiar with the difficulties actually encountered in the far simpler task of regulating private domestic industries in single countries, or to anyone who has won battle-scars as an active participant in any recent American attempts to set up effective consumer representation as a formal adjunct of regulatory agencies.

Among the more interesting portions of the book are the sections devoted to cartel policy conflicts between the Departments of Justice, Agriculture and State, and to the probable resurgence of industrial and financial concentration in Japan. The author's involved style makes it difficult at times to follow his argument.

Ben W. Lewis

Oberlin College

Der Aussenhandel zwischen marktwirtschaftlich organisierten und zentralgeleiteten Volkswirtschaften. By Willi Graf. (Zuerich and St. Gallen: Polygraphischer Verlag A.-G. 1951. Pp. 190.)

This book deals with the foreign trade between national economies organized on the basis of the market system of economy and those organized on the basis of direction by central authorities. The first section of the book gives a brief textbook-like description of the functioning of the private enterprise system and of foreign trade between market economies. The second section gives a description, in similar terms, of the functioning of a state-planned economy and of foreign trade between planned economies. In the third section which deals with the trade relations between capitalist and socialist economies, the author gives an able and well-informed analysis of the theoretical problems involved. However, a more concrete discussion of some of the actual trade agreements—in particular, the history of the post-war trade relations between Sweden and the Soviet Union, which well illustrates the practical problems arising in this connection—would have added to the value of the book.

When the book went to press (July 1950), the fate of the International Trade Organization was not yet decided. Since then, opposition from American

economic groups—both those favoring more liberal trade agreements and those favoring more protection—induced the Truman administration to refrain from submitting the Havana Charter for an I.T.O. to Congress for ratification. The Havana Charter constituted a compromise between the different groups of countries in the private enterprise camp. While provisions were made for state trading by socialist countries, these provisions were not a major point of controversy, quite aside from the fact that Russia was not represented in Havana, and that she would not have permitted her satellites, two of which had attended the Havana Conference, to join the I.T.O. in any case.

The inability of the free enterprise countries to accept common rules of desirable conduct in their trade relations shows that the antagonism between capitalist and socialist countries is only one of the basic problems in the field of international economic affairs. Within the private enterprise camp, the economically underdeveloped countries find themselves aligned against the countries with advanced industrial economies; and countries whose inability to deal effectively with the problems of inflation and overpopulation has put them in balance-of-payments difficulties find themselves aligned against the countries with "hard" currencies.

Dr. Graf makes it quite clear that the main difficulty in dealings with the Soviet Union and her satellites is not, as in the case of trading among private enterprise countries, the effect of trade on balances of payment. The planned economies of the Soviet sphere are import-oriented rather than export-oriented. They export only because they need funds with which to pay for needed imports, and they have no incentive to create an export surplus. At present, this is due to the high rate at which industrialization is being pushed, with the resulting emphasis on the use of resources for domestic investment. Moreover, the chances are that under a system of the Soviet type, the ruling group could always think up projects to which resources have to be diverted, even if the Soviet sphere were to attain so high a level of income that the proportion of income saved might reduce consumer demand below the level required to keep resources fully employed.

In this connection, Graf points out that it is doubtful whether Russia's distress export sales of raw materials and foodstuffs during the period of her first five-year plan, which coincided with the Great Depression, can be classified as dumping. The Soviet currency is entirely a domestic currency and any foreign exchange rates relating to it are arbitrary and fictitious. Thus, it is almost impossible to make cost comparisons between Russian-made goods and competing goods sold by private enterprise economies which would indicate whether a Russian export conforms to the definition of dumping.

The granting of most-favored-nations treatment and of tariff concessions is meaningless in the case of a government that can decide about the quantity, composition, and origin of its imports by actual purchasing policies rather than only by affecting import prices through the medium of tariff duties. Thus, the United States, in its trade agreements with the Soviet Union, insisted that Russia obligate herself to purchase a minimum amount of goods, stated in value terms (millions of dollars), from the United States.

The principal obstacle to trade between capitalist and socialist countries

appears to be the difficulty which private importers and exporters encounter in dealing with the foreign trading agencies of socialist governments which can act as monopolists and monopsonists. These difficulties are especially pronounced in the case of those desiring to export to the Soviet sphere. Like the giant corporation buying from small business enterprises, the foreign trading agency of the Soviet type is able to insist on relatively low prices in buying from enterprises in the capitalist countries. Moreover, the private firm which produces for Russian consumption, and expands its productive capacity in that connection, runs greater risks of potential excess capacity than if it produced for a diversified group of competing customers, withdrawal by none of whom would greatly damage its business outlook. The Russians are quite cognizant of the favorable position in which their monopsonistic power puts them. Graf quotes utterances by Mikoyan, the boss of the Soviet trading organizations, which show that the Communist regime greatly resents any attempts by private enterprisers to protect themselves by combining in cartel-like agreements for purposes of exporting to Russia. Mikoyan threatens such insubordinate capitalists with the withholding of purchasing orders from them. Of course, even if government arrangements or private cartels could be effective in equalizing the market power of private exporters with the market power of Soviet trading agencies, such arrangements would not be desirable because they mean a gradual expansion of the government-directed or cartel-directed segments in the free enterprise economies. Business circles in Germany and Japan which are hopeful of expanding their trade with Russia, Eastern Europe, and Red China may well pay heed to Graf's intelligent analysis.

Business Administration

Methods of Wage Payment in British Industry. By NORMAN C. HUNT. (London: Sir Isaac Pitman & Sons, Ltd. New York: British Book Centre. 1951. Pp. xiv, 160. $4.00.)

Methods of Wage Payment in British Industry is written primarily as a textbook for students of management. It is essentially a descriptive and nontheoretical treatment of the methods of paying rank-and-file workers.

Hunt starts his discussion of wage payment systems by casually commenting on the use of nonfinancial incentives and on the limitations of financial incentives. As examples of the former he cites the Hawthorne Experiments and the work of R. B. Wolf in an American paper and pulp mill. He considers the weaknesses of financial incentives to be: (a) social security from the cradle to the grave: (b) high taxation; (c) diminishing returns, and (d) the "restrictionism" of organized labor and organized capital.

The remainder of the book consists of a ten-page chapter on the time rate system, a four-page chapter on conditions of production most suited to a

system of payment results, and equally brief chapters on (a) the extent of payment by results, in British industries; (b) trade union attitude to payment by results; (c) the individual piece-work system; (d) problems of rate-fixing; (e) premium bonus systems; (f) group incentives; (g) merit rating, and (h) profit-sharing and co-partnership.

The main contribution of this book is found in the chapter on the extent of payment by results in British industries. Hunt quotes a 1949 survey by the Ministry of Labor which shows that 29 per cent of the manual workers in the industries covered by the study were paid by results. (The study did not include: office workers, shop assistants, travellers, clerks, most salaried workers, or those engaged in agriculture, coal mining, railway and shipping services, longshoring, the distributive and catering trades, the entertainment industries, commerce and banking, and domestic service.) After citing these statistics, Hunt succinctly describes the prevailing wage practices in some of the more important British industries, *e.g.*, iron and steel, shipbuilding, wood working, building, printing, textiles, etc. Unfortunately, Hunt sticks to a narration of details rather than making a critical analysis.

In the final chapter the author attempts to establish the criteria of a good incentive plan (*i.e.*, systems of payment by results). He lists the following: (1) Fairness: "The system must be fair to all concerned and contribute to the benefit of both employer and employee," (2) No rate-cutting. Mr. Hunt advises that . . . "in order to achieve accuracy in rate fixing, it will be desirable in many cases to employ time-study." (3) Simple: "It is essential that the wage incentive system be reasonably simple, so that the ordinary worker can understand it and estimate the amount of bonus he is earning. . . ." (4) Balanced. "It is important, too, that the wage incentive system should not upset the natural balance of wage rates within the plant. . . ." (5) Complaints. "Finally, there should be channels through which the workers can make enquiries regarding their wages, and, if necessary, lodge complaints or appeals."

The critical reader will wonder as to the meaningfulness of some of Hunt's criteria. Anyone who has attempted to administer wage incentive installations will realize that "fairness" is a fuzzy concept. The criteria used for judging fairness are numerous and are often contradictory. Case studies of wage incentive installations indicate that frequently management's value judgments as to what is fair or unfair are antithetical to the views of the workers.

The difference in point of view between workers and management is highlighted when one analyzes rate-cutting. Hunt's criterion of "No rate-cutting" becomes meaningless when one recognizes the existence of fundamental differences in definition. To Hunt, a rate cut occurs only where a standard of production is changed without a corresponding change in the method of production. From the point of view of the worker a rate cut may be defined as any decrease in rate of pay per unit of output. Hence, if, due to a mechanical improvement, a worker's output is doubled, and his pay is not increased in direct proportion to the increase in his output, he may argue that his rate has been cut. In actual practice one finds that workers frequently

compromise on what they are willing to accept as their "fair share" of increased productivity; however, very seldom do they accept Hunt's definition.

Hunt's book adds little to our understanding of the use of various wage payment plans. Part of this is due to his tendency to oversimplify, part is due to his failure to consider recent research on the efficiency of both financial and nonfinancial incentives (*e.g.*, he limits his discussion of nonfinancial incentives to a terse report of the study of behavior at the Hawthorne Works of the Western Electric Company conducted twenty odd years ago, and to R. B. Wolf's work done at the turn of the century). Part is due to Hunt's failure to analyze critically problems encountered in administering systems of payment by results. If he had made a rigorous study of the use of wage payment plans he should have seen that there are inherent in most systems of payment by results certain weaknesses which tend to limit their efficacy in paying rank-and-file factory workers. These limitations may be summarized as follows:

1. *Precise standards of performance cannot be established.* Machines, men and raw materials may vary from day to day and from hour to hour. It is practically impossible to completely standardize job conditions. Even if jobs could be standardized, there would be room for considerable debate as to "correct" standards. Weaknesses in the technique of time study (*i.e.*, human errors in reading the stopwatch, in leveling, and in determining fatigue and delay allowances), prevent the determination of exact and correct standards of performance.

2. *The use of a system of payment by results sharpens and accentuates differences between the goals of management and those of workers.* The theory underlying the use of wage incentives holds that a system of payment by results puts men into business for themselves, and in pursuing their own self-interest workers will increase their rate of output; hence, it is reasoned, wage incentives provide a technique for stimulating increased production by enabling workers to increase their earnings. The weakness of this logic arises from the fact that the worker's self interest not only prompts him to increase output, but also encourages him to fight for lenient standards of output. Wage incentives directly translate into money income differences of opinion as to appropriate standards of output and proper allowances for variations in job conditions.

3. *Wage incentives tend to distort traditional wage structures.* The use of a system of payment by results injects a dynamic element into the wage structure. Traditional wage differentials are often upset. From the workers' point of view such changes frequently appear illogical and unreasonable. This distortion of the wage structure seems to be inherent in the use of systems of payment by result in remunerating rank-and-file factory workers. It arises out of (a) differences in potential earnings on different jobs; (b) difference in the ability of workers on the same job, and of the individual worker on differents jobs; (c) differences in the pressures that groups of workers may apply in loosening up standards of output.

These debilities do not necessarily nullify the value of systems of payment

by results; but, they do indicate areas of study that should be covered in a book directed toward preparing students for management. Unfortunately, *Methods of Wage Payment in British Industry* describes only the more common systems of remuneration and the more frequently discussed weaknesses of each. It fails to probe deeply enough to come to grips with the fundamental problems of wage and salary administration.

WILLIAM B. WOLF

University of Chicago

Marketing Research. By DAVID J. LUCK and HUGH G. WALES. (New York: Prentice-Hall. 1952. Pp. viii, 532. $5.75.)

Reflecting the increasing interest in marketing research both among business men and our academic institutions, this introductory text in the field is designed to provide an "adequate and up-to-date treatment" of the subject that will serve the needs of practitioners and college students alike. Like most of its predecessors and contemporaries,[1] *Marketing Research* is concerned primarily with techniques and applications. It contains little that is new in either of these areas.

The volume is organized into four parts as follows: (1) getting acquainted with marketing research; (2) sources of marketing data; (3) techniques of marketing research; and (4) the application of marketing research. Each part is preceded by a brief introductory statement outlining the nature and significance of the material covered in the chapters which follow. The reviewer has little fault to find with the organization of the material. He believes, however, that Part IV could well have been enlarged without unduly lengthening the book. Too much emphasis on *techniques* and too little stress upon *applications* have characterized most textbooks in this field. Moreover, for convenience in use, he wonders why the "Suggested Readings by Chapters" are not listed at the close of each chapter rather than following the appendix. Furthermore, "Marketing Research as a Career" seems out of place immediately following "Organization of Marketing Research" and preceding "Secondary Data." A more logical place for discussion of the subject would seem to be at the beginning or the end of the book.

So far as the text matter itself is concerned, the reviewer was pleased with the recognition accorded the scientific method—"The one great criterion that distinguishes research from [non-research] procedure is *scientific method*" (p. 5); with the helpful figures and illustrations, particularly those in chapter 15; with the careful presentation of the various research techniques involved in the solution of economic problems—chapters 6-16; and with the wide range of reference material presented.

On the other hand, he was disappointed with the treatment of sampling, despite the additional material presented in Appendix A; with the lack of

[1] For example, American Marketing Society, *The Technique of Marketing Research* (McGraw-Hill, 1937); L. O. Brown, *Marketing and Distribution Research* (Ronald Press, 1949); R. Ferber, *Statistical Techniques in Market Research* (McGraw-Hill, 1949); M. S. Heidingsfield and A. B. Blankenship, *Market and Marketing Analysis* (Henry Holt, 1947); and J. H. Lorie and H. V. Roberts, *Basic Methods of Marketing Research* (McGraw-Hill, 1950).

greater explicitness in certain statements such as ". . . there remain ahead three steps without which the research will not bear fruit. One of these [is interpretation] . . ." (p. 323) (but the other two are not mentioned specifically); and with the lack of uniformity and completeness in footnote references. In many instances, neither names of articles from which quotations are taken nor page numbers in the periodical noted are shown.

The reviewer was disappointed that neither review and discussion questions nor short cases and problems related to the subject matter were included. Since he is convinced that effective instruction in marketing research necessitates active student participation in various projects involving the assembly of pertinent information upon which sound business decisions may be based, he hopes the authors will give proper consideration to including sample projects when *Marketing Research* is revised. It is possible, of course, that such projects are to be included in an accompanying *Teacher's Manual.*

It is all too easy to criticize, even on a constructive basis, and fail to recognize the contributions of writers in economic literature. Certainly *Marketing Research* reflects careful planning, conscientious if not complete documentation, and broad familiarity with the literature in the field. And it includes the major topics which an introductory course should provide. The authors, well-acquainted with other textbooks in the field, have sought to develop various concepts of marketing research which their teaching and business experience have revealed to be most important. Despite its minor shortcomings, there is little doubt that it will find favorable acceptance in the academic field and be used by numerous young men seeking a better understanding of the nature, scope, and applications of marketing research.

DELBERT J. DUNCAN

Industrial Organization; Public Regulation of Business

Lessons of the British War Economy. Edited by D. N. CHESTER. (London and New York: Cambridge University Press. 1951. Pp. xii, 260. $4.50.)

D. N. Chester deserves the thanks of economists for collecting these thirteen essays which review some of the principal developments in the control of the British economy during the war. Most of them were written by economists who served as wartime civil servants. The volume will be particularly valuable to American economists who do not have time to read lengthy official histories or detailed monographs: it is written in language which they can understand and addresses itself to problems in which they are interested. It is, however, a collection of reminiscences rather than an economic analysis of techniques of controlling a war economy.

Chester's own contribution, as a political scientist, is an essay which should give American readers some "feel" for the organization of the British government at "high levels," and the important ways in which its functioning differs

from that of the American government at similar levels. One of the problems which he discusses most interestingly, however, is the dilemma of the academic "temporary"—torn between the necessity to take broader, deeper, and longer views if he is to make the only contribution of which he is uniquely capable; and the apparent necessity to immerse himself in practical detail if he is to be effective. Crossing the Atlantic does not blur this dilemma. The impression left by most of the other essays in this volume is that it was usually resolved in London as in Washington by suppressing one's academic impulses. The "lessons" drawn by the authors are typically empirical and "practical."

Austin Robinson's essay on "The Overall Allocation of Resources" is a case in point. He divides the war into "phases," and traces from phase to phase the shifts in production, the associated changes in "limiting factors" on production, and the modifications which were required (or made) in allocation machinery and techniques. Examples of Robinson's lessons are: "We took too little account of the limits of local labor supply"; "there was . . . far too little appreciation of the possibilities of subcontracting."

Other practical examples are contained in essays dealing with specific problems of allocation and rationing by Ian Bowen (control of building), Percy Ford (allocation of timber), Richard Pares (work of a departmental priority officer), and W. B. Reddaway (consumer rationing). Bowen is particularly convincing (and "practical" in the best sense of the term) in arguing the necessity of a large measure of devolution in allocation machinery (a lesson the War Production Board learned slowly and reluctantly). Those who have had experience with similar schemes will not be surprised to learn from Bowen that the initial allocation of building labor was essentially an attempt to guess the *status quo,* and that subsequent changes usually involved decisions at the Cabinet committee level. Ford explains the special problems of allocating a material with a multitude of diverse uses and users. He is more aware than most of the authors that the suppression of the price system creates difficulties which are costly (*e.g.*, in scarce manpower) to overcome, if they can be overcome at all. Pares tells an interesting story of controls from the point of view of the individual department—in his case the Board of Trade, mainly responsible for civilian supply. His perpetual problem was to obtain from the various allocating authorities allotments of steel, timber, fuel, manpower, etc., which were reasonably in balance; but he thinks this problem was simpler for the Board of Trade than other Departments because they learned (a) that there is no "irreducible minimum" of civilian consumption, and (b) strict balance in the output of various consumption goods is not necessary. I would argue that there is no essential difference in these respects between civilian requirements and those of the services.

Reddaway has interesting and shrewd comments on problems of consumer rationing. On specific vs. group ("point") rationing he tells us that the British began with specific rationing because of presuppositions carried over from World War I; and shifted toward group rationing not mainly because of the economists' "freedom of choice" argument but because of the practical difficulties in having large numbers of separate schemes and coupons. He does

not think this trend can go all the way because the practical administrative difficulties in a general expenditure ration would be "insuperable."[1] On the problem of enforcement he writes the last word: "The successful enforcement of a rationing system and the avoidance of a black market is not primarily a matter of test shopping, flying squads and the like, but rather of devising a rationing system which will be relatively easy to enforce, and which will, indeed, to a large extent 'enforce itself' " (p. 192).

Two other accounts of successful operations based on a systematic devolution of functions are given by G. C. Allen (concentration of production policy) and A. W. Menzies Kitchin (local administration of agricultural production). Concentration of production in many civilian industries (to release labor and factory space) was achieved by a staff in the Board of Trade which was minuscule by American government standards. Essentially it operated by laying down general rules and objectives, and letting firms get together to form groups and concentrate themselves in accordance with the rules. Problems which would have been formidable or insoluble with a centralized approach (*e.g.*, defining industries, fixing compensation) almost solved themselves. Objectives were achieved speedily and flexibly. The control of agricultural output was in some respects similar. The Ministry of Agriculture relied mainly on manipulation of the price mechanism to establish the general pattern of production, and delegated to County War Agricultural Executive Committees authority to carry out its policies regarding drainage, tillage, use of fertilizers and imported feeding stuffs, the employment of farm labor, and farm management. By 1943, with a very moderate increase in the labor force (much of it unskilled) the net output of agriculture in the United Kingdom had increased by 70 per cent measured in calories or proteins, and by 30 per cent in money values at fixed prices.

E. F. Nash in his essay gives a less favorable account of the control of agricultural prices, which degenerated, in his opinion, to a form of collective bargaining. He also tells the story of the stabilization of the official retail price index with its 1904 weights and the associated story of the food subsidies. The problems and their solutions have an Alice-in-Wonderland quality. By 1947 Mr. Dalton was increasing the subsidies (and reducing the prices) on "high leverage" rationed items in the index like sugar and eggs to offset the effect of his increase in the cigarette tax!

Two essays discuss the impressive development of British official statistics during the war. Richard Stone's is essentially an historical digression on the White Papers on National Income and Expenditure which have accompanied every British budget since 1941. It is now difficult to realize that before the war there were no British official estimates of national income or of industrial production, and that, for example, no attempt had ever been made to project the balance of payments. Stone writes with the justified enthusiasm of one who played a primary rôle in correcting this rather incredible situation. G. D. A. MacDougall's essay on the Prime Minister's Statistical Section is really

[1] This is simply asserted (p. 185), but the reader can infer reasons from the discussion of enforcement and of "pointing" problems.

addressed to the adminstrative problem of providing a chief executive surrounded by autonomous and well-staffed departments with unbiassed information and disinterested advice. The same problem, of course, exists in the United States, and was "solved" during the war by a succession of individuals and ephemeral agencies in the Executive Office of the President whose relations with the President were highly personal. The Prime Minister's Statistical Section was apparently a similar sort of device, completely dependent on Lord Cherwell's personal relations with Mr. Churchill, taking its flavor from Cherwell, and disappearing with the change in government in 1945.[2]

MacDougall unfortunately says nothing about the substantive aspects of his work—presumably for reasons of security.

The most surprising and disappointing aspect of the volume is the almost complete absence of economic analysis—or even of curiosity about the relevance of economic science to the problems of allocating resources in a wartime economy. The wartime experiences of these economists led them to no reexamination of theory as, for example, J. K. Galbraith's experience in OPA inspired his penetrating essay on the "disequilibrium system."[3] The "lessons" learned by this group were almost exclusively "practical." My impression is that intelligent "temporaries" drawn from faculties of philosophy or classical languages would have emerged with similar "lessons." As evidence, the essay by Pares, a professor of history, is indistinguishable from this point of view from most of the rest.

I felt this lack of analysis most keenly in Austin Robinson's essay on the overall allocation of resources, where it would have been most appropriate. One would never know from reading this essay that there are economic theories about the optimum allocation of resources—that this is, in fact, what economic theory is about. "The golden rule of all planning," Robinson tells us on page 57, "is that it must be done in terms of the scarcest of the resources." This is a peculiar rule for an economist to regard as "golden." It is obviously right in an extreme and trivial case where one resource is scarce and all others free goods. In other cases it is not true that an optimum allocation can be achieved while ignoring constraints imposed on all resources save one. The golden rule of economic planning, as I remember it, is to make each resource equally scarce (in a precisely defined sense) in all alternative uses. This involves making all intermediate products equally scarce (in the sense that the marginal cost of augmenting each is proportional to its value). Robinson searches throughout his essay for an elusive "limiting factor," never defining what he means and apparently not realizing that if he could find one, it would constitute *prima facie* evidence of bad planning or bad management.

Robinson is tantalizing in a brief discussion of joint planning with the United States. Decisions as to what should be produced by each of the Allies "were in the main taken on pragmatic grounds. . . . In the later stages of preparation for the Normandy invasion attempts were made, it is true, by the

[2] It was resurrected by Churchill in a different form on his return to office in 1951.

[3] *Am. Econ. Rev.*, June 1947, XXXVII, 287-302.

Ministry of Production and American officials in London to work out the criteria for more rational decisions: Some calculations of considerable academic interest were made. . . . But while these calulations may have made some small marginal contribution . . . they had little or no major influence on the broader planning" (p. 47). The only interesting question to Robinson, apparently, is whether a rational economic calculus did in fact have a major influence; his readers will be interested in whether it should and might have had such an influence. Did the "pragmatic" decisions reduce the efficiency of allied use of resources by 1 per cent, 10 per cent, or 50 per cent?

Robinson's answer may well be that predictions regarding the future course of a war are so fraught with uncertainty that a rational calculus is inappropriate. Apparently for this reason he asserts: "It is by no means certain that more careful prewar analysis of an economico-statistical character would have produced substantially better results than the empirical methods which were in fact adopted" (p. 41); and elsewhere: "the power to make rapid change in the disposition of the nation's resources was the greatest war-winning weapon of all" (p. 36). I would agree emphatically with both these judgments, but draw a different moral. An analysis of an "economico-statistical" character based on a single set of single-valued expectations about the future course of the war would be quite likely to give worse results than "empirical methods." But surely our analysis does not have to be so restricted; we can plan for multiple contingencies and we can include flexibility as an essential objective. It is not apparent that the empirical methods used did in fact impart any special flexibility to the economy. If economics is now too retarded to make such analyses, it would seem to be an important lesson of our war experience that we need to develop the necessary methodology. Perhaps Robinson agrees; at least he is convinced that "there was nothing like sufficient background study in peacetime of the economic problems and limitations of conducting a total war" (p. 57).

There is remarkably little in these essays concerning relations between military production programs and the economy. This may be because there is no contribution from the Ministry of Production, and because MacDougall, who must have been involved in such problems, does not feel free to discuss them. Robinson complains generally that there was too little contact and exchange of ideas between the military planners on the one hand and those who were charged with thinking about the use of our total resources on the other; but he appears to have in mind merely the prevention of "overambitious developments by the supply departments and overambitious requirements by the Service departments." Neither Robinson nor any of the other contributors defines the economic problem broadly as the allocation of resources to maximize the accomplishment of military objectives, and shows how this requires simultaneous determination of military requirements and industrial resource allocations. (Ely Devons comes closest to this formulation in his essay on the tribulations of a coordinator of production programs in the Ministry of Aircraft Production.) The mere adjustment of an economy to meet military requirements which have been developed with only vague and casual

reference to resource costs and limitations cannot, except by accident, yield a good solution.[4]

It is perhaps symptomatic of the empirical bias of the authors that not one seriously questions the desirability of the complex system of direct physical controls which evolved in the course of the war, or attempts to explain the conditions in which controls of this type become necessary or preferable. That they are necessary is asserted in most cases, assumed in a few, and taken for granted in the rest.

By contrast there is, as we have seen, a good deal of argument and speculation about the right thing to allocate—manpower, materials, or "value." This discussion is not very illuminating because it lacks theoretical underpinning. Robinson and Bowen both argue that planning and allocating in money terms are unsatisfactory. While there are some practical difficulties associated with making allocations in pounds or dollars, I find the specific arguments they advance quite unconvincing. The argument on which Robinson places main reliance is particularly surprising: "wartime planning in monetary terms was in danger of leading one into the major error of treating all resources as uniform and mobile. In fact, in relation to the very rapid changes that were constantly being required, resources were extremely specific and extremely immobile. Even attempts to plan in terms of manpower were in danger of treating manpower as homogenous and mobile to an extent that was unrealistic. But if you were engaged in cutting the Ensa allocation in order to increase the supply of shipbuilding labor, you were at least under pressure to ask by what concatenation of intermediate transfers, both geographical and occupational, an actress might be transmogrified into a rivet boy. And the dangers of thinking in terms of homogeneous and mobile resources were not confined to manpower. The capital of the munitions industry was highly specific. There was no possible reason to think that 10 million pounds per annum of resources withdrawn from making explosives could be readily converted into 10 million pounds more of resources making aircraft" (p. 54).

Of course it all depends on the precise meaning one attaches to the word "readily." But the whole paragraph sounds less like an economist than like one of George Stigler's "engineers" arguing with an economist. It has been my experience with "practical" men who are not economists that they are too well aware and too much impressed with the specificity and immobility of resources. Economists have a quite special training which permits them to understand that an actress can be transmogrified into a rivet boy by intermediate transfers, and that a shift of demand to aircraft does release resources, directly and indirectly, which permits aircraft production to be expanded. Time is of the essence, of course, and it is a term in the equation about whose coefficient economists know much less than they ought. But no one who has studied the industrial history of the war can doubt that very rapid transfers are in many cases possible. Avoiding British and American examples, witness the re-creation of the German fighter aircraft industry within a few months of

[4] I have developed this point more fully in "Planning Defense Production," *Papers and Proceedings*, 62nd Annual Meeting of the American Economic Association, May 1950.

its destruction by bombs, or the quick recovery of the heavily damaged and distorted Russian industrial economy after the German advance of 1941/42. As Robinson so well states elsewhere: "the power to make rapid change in the disposition of the nation's resources was the greatest war-winning weapon of all." Unduly pessimistic assumptions about the mobility of resources can result in a failure to seize opportunities to produce new weapons, to exploit a success, to make good unexpected losses. Economists have a special responsibility to overcome this sort of myopic pessimism, which seems to me to be far more dangerous than the opposite risk that responsible executives will exaggerate the mobility of resources. Everyone knows that actresses can't make ships; only economists know that in a very significant sense it isn't so.

In reading these essays I looked hard for suggestions which might help to explain an observation which I with many other Americans made during the war. It is now a reasonably well-established fact that it takes two, three, or four times as many Englishmen as Americans to make a motor car, a radio, an airplane (production quantities), or almost any other industrial product. It seemed to me that in performing governmental functions this ratio was reversed—that the British made governmental decisions and executed them with staffs a fraction the size of ours. Now a part of this discrepancy is perfectly natural. One would expect the American government to be larger than the British for much the same reason that the British is larger than the Belgian—it has a larger and more complex country to govern. But it seemed to many of us that there was more to it than this—that the British in many cases at least, had smaller staffs because they operated more efficiently (and to some extent conversely, they were able to operate more efficiently because they had smaller staffs!).

There are a few clues in this volume—all fragmentary and practical, as one would expect. Hugh Weeks, in an essay on Anglo-American supply relationships, suggests two possible explanations in recounting the things in Washington which amazed him: (a) our excessively legalistic bureaucratic thoroughness: "the number and complexity of the forms required to claim for [Lend-Lease] civilian stores is still a legend and a nightmare among those who had to prepare them" (p. 73); and (b) the indiscipline of American civil servants and their departments: "American officials did not seem to be pinned down by the decisions of their superiors as the British were. On any complex problem various American departments would openly and loudly state divergent views" (p. 81).

Chester has some thought-provoking comments on the art of chairing committees and the technique of using committees in government. British committees sometimes work very successfully; it is notorious that ours never do.

One other clue has already been discussed—the apparent willingness of British government departments, in some cases at least, to devolve functions on other departments, local governments, or industry. Every American department I have known wants to do the whole job itself—as well as all related jobs. The "full faith and credit" which the Constitution demands that each State accord acts of other States is conspicuously not accorded any department

or agency of the federal government by any other. Perhaps the different traditions of the British permanent civil service are responsible for a more disciplined, less aggressive attitude toward aggrandizement on the part of British departments which places some restraints on bureaucratic "empire building."

But this is merely suggestive, and the volume contains many warnings that these differences should not be exaggerated. British departments are also autonomous and jealous. At several dozen points I felt an impulse to enter the marginal note "How like Washington!" Devons' whole essay, on the problems of coordinating the separate Production Directorates of the Ministry of Aircraft Production, and the Ministry's procurement program with the planning of the Air Ministry, could have been written with a few changes in names, titles, dates, and language, about almost any American department or agency with analogous functions. One quotation, from a section entitled, "Importance of Informal Contacts," will illustrate what I mean: "The planning directorate used two main lines of attack. Firstly, they engaged in the most subtle forms of spying they could contrive. The most effective was to find some person in a production directorate who had a grievance. . . . The other . . . was to discover officials either at M.A.P., the firms, or the Air Ministry who realized the importance of coordination and were not oversensitive about the prestige of their own directorate, cultivate their acquaintance or even friendship where this was possible, and use them as the main instruments of coordination, especially in an emergency when quick decisions were necessary" (pp. 116-17).

The superior efficiency of the British government is, in any event, no more than an hypothesis. It will, from the character of governmental functions, be difficult to verify by studies of the Rostas type. But with a third of national income passing to or through the government in cold war, and potentially much more in a hot, it would be difficult to think of more important and challenging problems than the measurement and improvement of the efficiency with which democratic governments perform their functions.

Industry Studies

Woolen and Worsted Manufacturing in the Southern Piedmont. By JAMES A. MORRIS. (Columbia: University of South Carolina Press. 1952. Pp. xiii, 197. $5.00.)

Mr. Morris' description of woolen and worsted manufacturing in the Southern Piedmont is in effect a statement of the competitive geographical advantages afforded this industry in the Appalachian Piedmont of Virginia, the Carolinas, and Georgia versus those available in New England. It is an attempt to answer the intriguing question: Does the recent growth and current

size of the industry represent the beginnings of another large-scale migration similar to that of the cotton textile industry from the historical center in New England to the Southern Piedmont?

Contrasted with "a decrease in the number of all types of equipment except combs between" 1939 and 1951 for the woolen and worsted manufacturing industry as a whole (pp. 69-70), thirty-one new plants were established in the Southern Piedmont between these dates (p. 82). This development differed from the growth of the cotton textile industry in the South, for it resulted largely from the opening of branch plants by New England firms instead of the creation of new firms by southern capital and management as was the case in cotton (p. 70). The Census of Manufactures in 1947 stated that 4.6 per cent of the establishments, 6.7 per cent of the production workers, and 6.2 per cent of the value added by manufacture for the industry as a whole were located in this area. The plants represented by these statistics reflect only a portion of the functions carried on by the industry. Total operations involve cleaning, combing, spinning, and weaving; because it is unprofitable to maintain cleaning and combing operations for a small secondary market, the work performed in the South has been confined almost exclusively to spinning and weaving. This means that any cost or other advantages enjoyed by the South must more than offset not only the inertia and costs of establishing a plant in a new environment but also the higher costs of securing raw materials from the scouring and topmaking plants in the Boston area and the expenses of shipping products to the New York City market. Cross-hauling of semi-finished and finished products constitutes the most significant adverse cost differential to operations in the South. This disadvantage amounts to an increase in cost of roughly 1 per cent of the value of the product (p. 148).

Offsetting this cost disadvantage the Southern Piedmont generally offers savings in fuel costs, state and local taxes, and power rates. Apparently a greater source of advantage at the moment is the differential in labor costs. A high rate of population increase and a continuing displacement of agricultural workers furnish a large supply of labor. Absence of an industrial tradition and an aversion to unions make the worker willing to perform scientifically determined work loads at wages prevailing in the cotton textile industry instead of being bound by work-load mores and wage rates of the unionized woolen and worsted industry in New England. The wage rate customs in New England have perpetuated a substantial differential between cotton textile and woolen textile workers. Therefore, the woolen industry in the South has not only a possible geographic wage advantage in the rates paid for similar jobs but also the additional advantage of the customary rate differential between cotton and woolen wages paid in New England (p. 109). Thus, wage rates, smaller fringe benefits, lower payroll taxes, and greater worker flexibility seem to provide the South with a comparative cost advantage in this industry at the moment.

The difficulties of assessing actual cost differentials are imposing; they are so great, in fact, that some of the manufacturers surveyed by Mr. Morris said that they opened Southern plants to learn how their competitors were under-

selling them (p. 170). Since two-thirds of the plants beginning operations between 1939 and 1951 were branches of existing New England establishments (p. 83), a quest for comparative cost information may have been a motive in a number of cases.

From the evidence presented here, at least three avenues of future development for this industry seem possible: (1) a large-scale migration of woolen textiles to the Piedmont; (2) a reduction of labor costs in New England through a modification of the attitudes of workers and their leaders concerning work loads, new machinery, and wage rates; and (3) an amalgamation of the woolen industry with the cotton and synthetic fiber industries to form one "textile" industry with common technological and labor standards. Morris apparently believes that the first of these possibilities will materialize providing no substantial changes occur in the present situation. The recent arbiter's settlement by Walter Gellman of Columbia University providing an 8½ cent wage *cut* for the pattern-setting New Bedford-Fall River textile workers increases the probability of the second proposition. The long-run technical development of new fibers and blends and the apparent feasibility of fabricating some of these on existing or modified cotton-working equipment lends credence to the third possibility.

Morris has amassed a noteworthy amount of statistical and other information concerning the Southern segment of the woolen and worsted manufacturing industry. It is evident throughout that he is intimately conversant with the technical and managerial workings of the industry. It is unfortunate that he could not have reworked this material to clarify the findings and to emphasize the core of the argument. The fault here is, in the main, common with other theses and dissertations, for the system producing them tends to encourage temporizing statements and innocuous conclusions.

LLOYD SAVILLE

Duke University

The American Cigarette Industry. By RICHARD B. TENNANT. (New Haven: Yale University Press. 1950. Pp. xxvi, 411. $5.00.)

This is definitely one of the better industry studies. The author has made intelligent use of economic theory and statistical techniques to bring the study into clear and sharp focus. The book is well written and, for the economist, has the virtue of being organized in such a way as to be most easily assimilated.

A very useful one-hundred page history is followed by a crosscut analysis of the cigarette industry since 1911. The salient characteristics are: demand, moderately responsive to real income but quite insensitive to price and advertising expenditures; supply of leaf tobacco, completely inelastic for a crop, moderately elastic from year to year; manufacturing cost, horizontal average variable cost and no appreciable economies of scale. The reasonable probability of most of these characteristics is established by a judicious combination of theoretical reasoning, analysis of historical incidents, and statistical analysis. Least well established are industry demand and costs.

For some unexplained reason, the major statistical evidence on demand consists of the regression of per capita *tobacco* consumption rather than cigarette consumption upon per capita real income and time. From the small residual variability, 3.3 per cent, the author infers low price elasticity. It is dangerous to derive the shape of the demand curve from the fact that changes in consumption are highly correlated with variables likely to produce shifts, particularly when price changes are confined to a narrow range, are probably correlated with income, and are likely to be accompanied by offsetting changes in advertising. However, partly because of other evidence, it does seem plausible that price changes of the customary magnitude have had little effect.

For cigarettes, Tennant merely plots relative per capita consumption (pounds of cigarettes to pounds of tobacco) logarithmically against time. Visual comparisons with various price and advertising series are used to suggest the insensitivity of cigarette consumption to prices and advertising. It is assumed that these variables can have an effect only by increasing consumption relative to other forms of tobacco. This reflects overconfidence in the regression for tobacco consumption. Some of the "explained" as well as the "unexplained" variability may have resulted from the actions of cigarette manufacturers. Furthermore, in the relative consumption curve percentage changes in cigarette consumption which represent changes in total tobacco consumption are understated to an extent which has increased greatly with the rising importance of cigarettes. Since the visual comparisons are far from conclusive, it is unfortunate that the author chose a form of presentation favorable to his results.

In discussing costs Tennant strives overly hard to wring conclusions from unwilling and unreliable data. Horizontal average variable costs are assumed without discussion (p. 354) and in the face of a sharp rise in labor costs for brands whose sales declined between 1941 and 1942. Possible short-run cost variation and the probability that some brands were produced in several factories becloud the author's attempt to determine economies of scale by regressions of unit labor cost and unit overhead upon brand sales. These apparently overlooked difficulties in the data make one reluctant to accept the conclusions.

With respect to price, oligopolistic uncertainty is markedly less than in comparable industries. Each firm recognizes and, what is more important, knows that its rivals also recognize that there can be no appreciable difference in price except temporarily. According to the author, uniformity is brought about by the price leadership of Reynolds, especially for the more difficult upward rises. Since 1931, however, American has led two strategic reductions and two increases, and Liggett attempted an unsuccessful increase in 1946. Any one of the Big Three can announce a higher price and, if not followed reasonably soon, can rescind it without affecting the actual price to distributors. It seems doubtful whether such price leadership as existed has been necessary to maintain cooperation and prevent competition. Any firm can in effect propose a price change and, if not seconded, can withdraw the motion. When it still had the largest sales volume, Reynolds was more likely to receive seconds than any other firm, but American has done as well in recent years. Tennant's conclusion that "the behavior of competitors has been

easily foreseeable" (p. 364) seems overstated. What is foreseeable is the approximate identity of price, not necessarily the precise set of moves and countermoves which will bring it about.

It is unfortunate that more of an effort was not made to analyse advertising strategy and its relationship to price and costs. There are some interesting and unexplained problems.

Despite the antitrust conviction, Tennant constructs a plausible hypothesis of noncollusive behavior. Since profits are undoubtedly above the mythical competitive level, a sharp dilemma is presented for public policy. Fragmentation would have significant effects, the author believes, only if carried far enough to produce Chamberlinian monopolistic competition. By analysing the previous dissolution and the trend in distribution costs, he presents a persuasive case for believing that the increased cost of selling would probably outweigh the reduction in profits. The author considers a limitation on advertising more promising, since it would attack both the principal waste and the major barrier to entry. I doubt, however, that entry would be facilitated, since the large companies could adopt a lower long-run price level. With established brand preferences, probable cost advantages, and a restriction upon the advertising of potential rivals, the position of the large firms might be even less assailable. But prices would be down and advertising would be less, the result apparently produced by the recent prosecution. In fact, the author concludes somewhat reluctantly that the best public policy is continuation of the threat of prosecution.

Although the study is distinguished by a competent use of theory, there are two exceptions. At times theory appears to become a strait jacket, and conclusions are stated in unnecessarily extreme form. Also, in using his results as a defense of marginalism, the author slips into operationally meaningless propositions. Marginal analysis is regarded as valid by definition whenever any problem of maximization arises, and an interest in profits is confused with an interest in their maximization (p. 364).

More recently W. H. Nicholls has analysed the same industry, but he has concentrated heavily on price policies and has not attempted a broad industry study.[1] The characteristics of demand which Tennant made a very careful effort to determine, Nicholls introduces without discussion. The authors disagree on the sensitivity of total cigarette demand to income and advertising. Nicholls presents much more of the original data on price decisions and the issues of the trial. Although Nicholls gives a more complete and better balanced analysis of price policies, the authors seem to be in substantial agreement. Both advance noncollusive explanations of behavior, but Nicholls discusses more cogently the dilemma for public policy. Nicholls is somewhat more favorable to dissolution, but he does not consider as fully as Tennant does the probable rise in costs. He does, however, correct for the defects in Tennant's limitation upon advertising by proposing a tax on advertising, the base being the size of firm. By piecing together these two excellent studies,

[1] William H. Nicholls, *Price Policies in the Cigarette Industry* (Nashville, 1951). Reviewed in this journal, June 1952, pp. 461-63.

economists can get a deeper insight into the cigarette industry than into almost any other.

DANIEL C. VANDERMEULEN

Claremont Men's College

Men, Meat and Miracles. By BERTRAM B. FOWLER. (New York: Julian Messner, Inc. 1952. Pp. 245. $3.00.)

This book is an excellent popular survey of the modern American livestock and meat industry by a man whose newspaper training, journalistic experience, and special studies and books on various aspects of the cooperative movement in America—agricultural and otherwise—have given him a good background of knowledge and understanding. In less than 250 pages of eighteen pleasantly written descriptive and interpretative chapters, the author has done several useful things for the student of our economic and business history.

First, he has drawn some realistic pen pictures of the men who developed the modern meat packing industry of national and international scope. Morris, Armour, Swift—the great innovators—are here brought to life and interpreted sympathetically. So, too, are some of the characters who made the Chicago stockyards and other livestock markets. The relation of the industry to the agricultural growth of the West is made clear. The significance of the industrial revolution of the generation after the Civil War is emphasized, using the meat industry for illustration. Indeed, all through the volume the author drives home the debt we owe to the free enterprise system, its traditions and ethics, by examples from the customs and practices of this industry where so much has been carried on by word of mouth—the honor system—rather than by written contract.

In several chapters the author is at pains to clear up some misconceptions about the meat industry. He shows how it was the very fact of the expanding national meat industry that brought inevitably the evolution of the present system of federal meat inspection. The usually accepted story is that it was forced upon the industry by the mere publication of such lurid and unjust books as Upton Sinclair's *The Jungle,* a book which has been given entirely too much credit by serious historians. Likewise, he devotes an entire chapter to the myth of the "Beef Trust." He indicates how understandable was the rise of the myth because of the fact that the distribution of meat and meat products dealt with such an overwhelming majority of the people through local meat markets. Therefore, the consumers were out of direct touch with the packers themselves. The packers were caught between the livestock producer on the one hand and the consuming public on the other.

Finally, with his prior interest in cooperation, it is natural and logical that the author should devote the latter half of his volume to the development of cooperation both within the meat industry itself, and with livestock producers. Intra-industry cooperation made the industry more efficient in production, in distribution and in the carrying on of industry-wide research with the University of Chicago. The Institute of American Meat Packers, since 1940 known as the American Meat Institute, made the problems of the industry

more widely understood by the public. Also, there has been effective cooperation brought about between the industry and the great national livestock producing associations. All this is told through what is essentially a series of biographical chapters about Thomas E. Wilson, who has been the recognized leader of the meat industry during the past generation. It was his personality, prestige and persuasiveness that did much to establish the meat industry's trade association, and the National Livestock and Meat Board, and rendered so successful and beneficial to the nation the 4-H Club work among millions of young farm boys and girls during the last quarter century.

Perhaps the author has given credit to too few individuals in this national industry; but to point up some few fundamentals, and to drive home some basic truths about one of the greatest modern industries of this country, his method is effective. While there may be a tendency to leave an impression of a little more altruism than was actually the case, yet this book helps to redress the balance after a series of volumes by writers who have been too critical, without any practical experience of business to enable them to see industrial problems as they must be seen by those who have to solve them. We need both points of view and both kinds of books. The present volume is a valuable statement of the laissez-faire view. All it lacks is an index, and some additional documentation.

Land Economics; Agricultural Economics; Economic Geography

Agriculture and Economic Progress. By E. M. OJALA. (London and New York: Oxford University Press. 1952. Pp. 217. $5.00.)

Since the days of Malthus, economists have realized the importance of efficient food production and marketing. But they have given greater attention to these problems in the past decade than ever before. The Food and Agriculture Organization has presented evidence that economic progress is being retarded in many parts of the world by inadequate diets. Mr. Ojala's book summarizes some of the evidence on this period, and proposes policies aimed at increasing the world's supply of food, and distributing it in such a way as to overcome the worst dietary deficiencies.

This is a very large problem. Ojala states, for example, "It has been estimated that if production goals were based on full physiological requirements, the world production of the more expensive foods of special value for health would need to be doubled." He apparently refers here to animal products and to fruits and vegetables. Although smaller increases would satisfy the needs for food grains and root crops, it is clear that world agriculture would have to be expanded greatly to meet all food needs.

In his first chapter, Ojala reviews the findings of Colin Clark that economic progress is associated with a decline in the proportion of the population engaged in agriculture. The second chapter, "Concepts of Economic Welfare,"

includes a discussion of agriculture's contribution to economic welfare. It is pointed out here that the retail price of food includes payments for processing, transporting, packaging, delivering, and so on. Ojala contends that these payments should be eliminated, and that "to measure the contribution of agriculture alone to the community's economic welfare, the procedure must involve weighting agricultural output by the value which the community places upon that output as it leaves the farm."

Chapters 3, 4, and 5 review the statistics of agriculture and of other segments of the economies of the U.S.A., Sweden, and the United Kingdom. This analysis forms the basis for conclusions drawn in the remainder of the book, concerning the relation of economic progress to industrial patterns, to consumption patterns, to agricultural population and incomes, and to price levels.

The final chapter deals with policy. It is pointed out that "there is a fundamental problem of agricultural incomes . . . agricultural producers individually have, on the average, been constantly and badly underpaid for their services," due to many factors, including the low price-elasticity and the low income-elasticity for food. He points out that some kinds of price supports may be needed to encourage adequate food production, but indicates the need for flexibility in the agricultural labor force in order that submarginal farm workers may find more productive work in cities. He concludes that "the primary concern of world agricultural policy should be to increase the *efficiency of production* everywhere, particularly in the growing and supply of foodstuffs."

FREDERICK V. WAUGH

Washington, D.C.

The Canadian Grain Trade—1931-1951. By D. A. MACGIBBON. (Toronto: University of Toronto Press. 1952. Pp. ix, 227. $4.50.)

This is the second book that Professor MacGibbon has written on the subject of "The Canadian Grain Trade." The first appeared in 1932 and brought his review and analysis of the market organizations and development of exports for Canadian grain through World War I and the decade of the 1920's. In that period Canada came of age as a world exporter of wheat, and with the active market demand for her increasing production a feeling of considerable assurance about the future had begun to develop.

The present volume, covering the twenty-year period 1931-51, not only brings the earlier volume up to date but it provides an unusual account of the step-by-step control that the Canadian government has assumed in regard to the grain trade in that country. Beginning with the impact of the world economic depression of the early 1930's, especially upon the three prairie provinces of Canada that had concentrated upon wheat production, it chronicles the developments that led to the creation of the Canadian Wheat Board that has become one of the foremost world grain-marketing monopolies of the present time. Starting with continued declines in world and Canadian wheat prices in 1929 and 1930 that adversely affected the credit position of the Pool organizations and in turn the banks that had been providing the financing for the crops, a joint appeal was made to the federal government

for aid. The assistance was granted on the understanding that a central selling agency be established and a government-appointed manager be placed in charge. The crisis lasted longer than expected; then World War II started and the Wheat Board further extended its rôle of operation through the war and postwar food crisis period. Today the Board seems to be rather generally regarded as a permanent part of the Canadian grain trade.

This point deserves special mention in the opinion of the reviewer because it shows how what was expected to be a temporary intervention on the part of the government led to the creation of a state monopoly marketing organization of Canada's principal export industry. MacGibbon's book, in fact, may be regarded as a case study for those interested in government controls and state trading. As such, it should have a wider audience than those concerned with developments in Canada or in commodity activities relating to grain and especially wheat.

In 1929 MacGibbon, who had been professor of political economy at the University of Alberta for many years, was appointed a member of the Board of Grain Commissioners for Canada—the government agency responsible for administering grain standards and regulatory activities. He served as a Commissioner for twenty years when he again returned to academic life. During these two decades, however, which closely correspond to the period covered by his present volume, he was in a position to observe Canadian grain trade developments closely. This fact, no doubt, accounts for much of the detail included in the book which makes it rather slow and difficult reading though at the same time a very useful reference source on the subject for this period. The Board of Grain Commissioners, it should be noted, is a separate and distinct agency from the Canadian Wheat Board, and his extensive references to Wheat Board operations are as an observer, not an active participant.

Among the points given special emphasis in the present book are the International Wheat Agreements of 1933 and 1949, the British wheat agreement (a bilateral contract), and the various organizational segments of the grain trade. These include, in particular, the Canadian Wheat Board, its establishment in 1935, its operations during the war period and postwar development (little detail after 1949-50); the three Provincial Pool organizations and their growth, the United Grain Growers Ltd. and the independent companies, and the Winnipeg Grain Exchange. With these grain trade organizations so widely different in character, yet many of them highly competitive in their efforts to participate in marketing Canadian grain, it may be expected that there will be some differences of opinion about the author's treatment of these sections, particularly among the various groups represented. The relative effectiveness of the respective types of marketing operations and organizations in Canada continues to be a very controversial subject. If another Royal Commission (the last commission study was made in 1936-38) were to investigate the problem of Canadian grain marketing today, it would be interesting to see how the various issues and organizational forces would be compromised. It is notably true, however, that producer groups in Canada as in the United States appear to be almost unanimous in the desire to have some

form of support price that will prevent free market prices from declining beyond certain limits.

While most of the book is devoted to a factual commentary, the author does include some personal interpretations and conclusions. Among these the following selected brief statements appear timely and of general significance and also seem to reflect in summary form much of MacGibbon's point of view about Canada's grain trade.

> Canada is so deeply committed to an export trade in wheat that any developments in this field of international trade are of the highest importance to her. . . . But it must be recognized that neither the outcome of the British wheat agreement nor the prices currently being obtained from sales made under the terms of the International Wheat Agreement provide evidence that long-term contracts of this nature are advantageous to the producer.
>
> The maintenance of the Canadian wheat export trade on a sound basis requires wheat production in areas capable of growing wheat of high quality at relatively low cost, the handling of stocks in the least costly method possible without deterioration of quality, and a sales policy of offering wheat at prices "as low as is consistent with actual cost of production." Regard for these factors in the past largely accounts for the important position Canada now occupies in international wheat trading, and it lies within Canada's own power to continue to be guided by this fact. Canada, however, is only part of an international trading community in which the wheat trade is an important item. International trade will languish if nationalistic restrictive policies impair it. For the Canadian West the most propitious circumstances for the continuance of its export trade in cereals are those that make for the freest possible international exchange of goods and services.

When the reviewer finished reading the book and started to reflect upon the subject of the Canadian grain trade and particularly the phases with which he has had personal contact over many years, there were a number of points that seemed to call for special comment. He has selected three that may be of more general interest. The first relates to statistical material. The reviewer had hoped that the book would have a comprehensive set of statistical tables and possibly charts covering various aspects of the Canadian grain trade during the twenty-year period. Only four short tables, however, are included and these are confined largely to a limited period and subject matter. Export data about Canadian grain or Canada's place as a world exporter is particularly inadequate for those interested in this aspect of the grain trade in that country. On the other hand, almost every paragraph is studded with statistical data or comparisons. Prose statistics, while of some usefulness, present real problems in usability for reference purposes or effective analysis, and especially in readability.

The second point concerns the Canadian Wheat Board. Its operations which cover much of the period of the book are discussed in a very impersonal manner. No doubt the author had his reasons for this type of treatment, but in the opinion of the reviewer the Board and the personality of its Chief Commissioner, Mr. George McIvor, have been so closely interwoven during most

of the Board's official existence that it is hard to separate them. The history of the Board and its operations might have been vastly different from what Professor MacGibbon has recorded had someone else been its Chief Commissioner, and particularly if political influence had been permitted to affect its operations as so often happens in agencies of this type. There are few government organizations anywhere, especially of the size and volume of business handled, that can point to a longer untarnished record than the Canadian Wheat Board. This factor should not be overlooked or underemphasized in any evaluation of the Board, particularly by other governments that may be interested in Canada's experience in this type of grain trade organization.

Thirdly, this period, and notably the years following World War II, have emphasized some of the weaknesses in the Canadian grain export situation, particularly in meeting world emergency needs. Notwithstanding the major export rôle played by Canada during much of the inter-war period, it was the U. S. ability to produce and export larger quantities of grain that saved the world during the food crisis period. Among the weaknesses that have become apparent are the limits on exports due to domestic transportation facilities, and the vulnerability from weather conditions to the concentrated production in western Canada. A policy of maintaining reserve stocks could do much to minimize the effects of annual crop variations, but Canada has usually proven to be an aggressive seller regardless of the status of stocks.

The story of the Canadian grain trade is a very interesting one and it is still being written. MacGibbon has brought his account of the story up to date, and it should prove helpful to those interested not only in a better understanding of past developments but also in having background for some of the important chapters that are likely to be written in the period ahead.

GORDON P. BOALS

Washington, D.C.

World Economic Geography—An Introduction to Geonomics. By GEORGE T. RENNER, LOYAL DURAND, JR., C. LANGDON WHITE, and WELDON B. GIBSON. (New York: Thomas Y. Crowell. 1951. Pp. x, 758. $6.00.)

There is surely no lack of agreement that the beginning student of economics is invariably woefully innocent of any significant body of factual information relating to economic matters beyond his personal and very limited immediate experience. That he should know much more than he does about the economic resources of his own nation, and of the world, and of the physical characteristics of specialization in production, trade, and transportation, seems obviously desirable. Precisely what the student should know, for what purposes, and how he should acquire this information are matters on which very great differences of opinion and practice exist. One solution, followed particularly in undergraduate schools of commerce, is to require a course in economic geography, with the expectation that the student, in the process of acquiring a fund of factual information, will develop also some appreciation of economic life as consisting, as the authors of this volume write, of "superimposed and intimately interrelated physical, economic, and cultural patterns."

If our authors are aware of "interrelated patterns," they state also that "the great problems of the world are basically matters of economic geography and

cannot be properly understood in any other terms." The expectation is aroused that the subject-matter will be broadly and inclusively defined with appropriate analysis of economic and cultural patterns in the light of physical resources. Were such the case, this might justify the claim that this is a "really new type of college textbook." In fact, the performance is conventional and the book is more adequately described as one which "develops the more common principles and generalizations of economic geography in the light of an orderly and relatively full presentation of the great industries of mankind."

The volume is indeed a relatively full presentation of the world's more important resources. After a brief and elementary discussion of the relationship of men and resources under the title of Geographical Premises, it plunges, in Part 2, into the discussion of well over a hundred basic commodities and commodity classes, occupying close to five hundred double-columned pages. It begins with those agricultural products characteristic of the rainy tropics and continues with chapters on the products of each of the great climatic regions. Individual chapters are devoted to forests and to fisheries, and other oceanic products. Part 3 covers the basic minerals and then moves on to deal with the geographic distribution and characteristics of the major manufacturing industries. Part 4 covers transportation and commerce, opening with a chapter on the division of labor, followed by one on the principles governing the exchange of commodities, continues with four chapters on the major forms of transportation, and concludes with a very brief discussion of the forms of social regulation of trade.

In the discussion of resources and commodities, emphasis is on the physical factors which relate to supply and utilization. References to costs, values, and quantities are largely summarized in charts and maps in very general terms; the volume will do little to develop the student's ability to think quantitatively. Relevant historical developments are given unusual extensive emphasis, but the institutional organization of the societies which use the resources and produce the goods discussed are treated very lightly or ignored.

Those who wish to introduce beginning students to an extensive body of factual information will find this volume very useful. Even for that purpose, however, the book would seem to include too few indications of the reasons why facts are presented, too few clues to aid the student in developing his judgment as what is more or less important. The student who masters the material presented will possess much information pertinent to such problems as those of present-day Europe or of the underdeveloped countries. The analytical tools necessary to the utilization of such information will have to be supplied from some other source.

Washington, D.C.

Labor

The Danish System of Labor Relations: A Study in Industrial Peace. By WALTER GALENSON. (Cambridge: Harvard University Press. 1952. Pp. xii, 321. $4.50.)

Denmark has had comparative industrial peace and a highly centralized

collective bargaining system for fifty years. The record of this achievement and the problems that have developed within recent years as Denmark's terms of trade have become less favorable are thoroughly explored in this second study[1] of industrial relations in a Scandinavian country by Walter Galenson, who served as labor attaché at the American embassies in Oslo and Copenhagen in 1945 and 1946.

The Danes achieved stability in industrial relations much earlier than their Scandinavian neighbors, although the pattern was similar. The Federation of Labor, now representing nearly 90 per cent of the workers in manufacturing, construction and transportation and communication (and smaller percentages in other industries), was formed in 1898—the same year in which the Danish Employers' Association was established. The latter is even more centralized than the Federation of Labor, which has been plagued by internal differences between the skilled craft unions and a Laborer's Union of unskilled and semi-skilled factory workers, totalling 38 per cent of the Federation's membership. A test of strength between the two central organizations came during "the great lockout of 1899," when the employers, "aroused by the increasing trade union aggressiveness occasioned by favorable employment conditions, decided to wage a preventive war before their opponents grew too strong" (p. 98). The objective was not to crush unionism, however, and after three months the "September Agreement" was signed, laying the groundwork for the subsequent pattern of peaceful Danish labor relations. Similar agreements did not come until 1935 in Norway and 1938 in Sweden.

Collective agreements in Denmark are predominantly nation-wide, and they generally have a common expiration date (March 1). Significantly, the initiative for these developments came from the organized employers, rather than from the unions, as is generally the case in the United States. The difference is explained by the smaller relative size of Danish firms confronting powerful national unions. Individual employers have delegated full responsibility for negotiations to full-time professional staffs in the central association, although recently there have been proposals to strengthen local bargaining on matters of local interest. Galenson believes, however, that increased independent bargaining is unlikely because of the Employers' Association's probable unwillingness to abandon the "sympathetic lockout" which prevents strong unions from playing one employer off against another.

What have been the effects of this centralization in collective bargaining? Industrial peace is the outstanding one, and in this the Danish record is better than either the Norwegian or the Swedish. But peace has not come without increasing government intervention, despite the elaborate collective bargaining machinery. Governmental mediation is highly developed in Denmark, dating from 1910, and the mediator takes an active rôle in proposing a settlement. "The national wage movements of the last three decades have almost without exception reached at least the mediation phase of collective bargaining" (p. 127). Since 1932, mediation has failed in ten cases which

[1] The first was *Labor in Norway* (Cambridge, Harvard University Press, 1949).

were settled only after further government intervention involving *ad hoc* compulsory arbitration or enactment of the mediation proposal into law following rejection by (with one exception) the employers. Galenson notes: "The growth of centralization in collective bargaining certainly renders it less likely that the government will refrain from intervention" (p. 137). Sweden's experience, however, is still an exception to this generalization. Both countries, it should be noted, have a Labor Court to adjudicate disputes arising under collective agreements.

The economic effects of centralized collective bargaining are less apparent. The greatest gains in real wages came after both world wars, when there was wage-price inflation and full employment. "Whether as cause or effect, both these periods were marked by a considerable radicalization of the trade union movement and aggressive union wage policy" (p. 162). Union strength was evidently a factor in resisting wage reductions, for in the period 1930-37 the unions maintained money wages unchanged in the face of an adverse shift of the terms of trade between Denmark and the rest of the world, resulting from a relative decline in the prices of agricultural products, which Denmark exports.

The shift in the terms of trade accounts principally for the failure of Danish real wages to keep pace with those in Norway and Sweden, although there has also been a lag in Danish labor productivity. The reasons for this are more complex, but the very factor which helps make Danish labor relations orderly also apparently tends to restrict industrial efficiency and expansion. Galenson calls this "the spirit of corporatism" (p. 266). Businessmen are addicted to price and market agreements in the sheltered domestic market, unlike their Norwegian and Swedish counterparts, or the Danish farmers, all of whom must complete in world markets. "For their part, the trade unions have abetted restriction and contributed to the failure of industrial productivity to rise more sharply by insisting upon the maintenance of an archaic labor market structure" (p. 267). Recently, however, the Danish unions have taken productivity more seriously, through establishing labor-management production committees, participating in a commission to improve utilization of manpower in the face of closed jurisdictions of skilled crafts, and general discussions of ways to increase industrial productivity.

Another economic effect of centralized bargaining in Denmark is a stable wage structure. Powerful unions have apparently not been able to "distort" the structure, as is sometimes charged in this country. The metal-trades agreement sets a pattern which is generally followed in the other centralized negotiations, and prevailing wage relationships are largely maintained. The principal exception is the narrowing of the skilled-unskilled differential, which was realized under central bargaining. Galenson concludes that "the absence of centralized bargaining would have resulted in greater scrambling of craft wage differentials and in less equalitarianism" (p. 186).

The Danish labor movement, unlike the Norwegian or Swedish, has been forced to rely principally on collective bargaining for the achievement of its economic goals. The Farmers' Party is relatively stronger in Denmark, and

although the Socialist Party, with which the unions are allied, is larger, it is still a minority party. Thus, taxation, price controls, subsidies, and government regulation of investment cannot be utilized as they are by the Norwegian and Swedish labor parties which enjoy stronger positions of control. For the same reason, the Danish unions have not had to face the impact of these programs on their collective bargaining rôle when a labor party is in power.

The Danish labor relations experience is instructive on the advantages and costs of centralized collective bargaining. Professor Galenson has again helped American students of labor economics and industrial relations to gain new insights into our own collective bargaining experience by this type of comparative study of a labor movement. As Professor Slichter rightly points out in a Foreword to the book, "Careful case studies are needed to produce a reliable basis for generalizations about why men organize and why different trade-union movements develop different objectives, policies and methods. The accumulation of the necessary case studies is bound to take years."

This reviewer would have liked more analysis of the Danish entrepreneurial system, its outlook and policies, and its relation to the kind of labor movement which evolved. There is little mention, for example, of the ways in which Danish employers have handled labor relations at the plant level, their attitudes toward the shop steward system that has developed, or their behavior under the protection given by the September Agreement to management prerogatives. But with the rich offering already provided, these omissions are not serious. This study, and the earlier one on Norway, set a high standard indeed for other students of foreign labor movements to achieve.

CHARLES A. MYERS

Massachusetts Institute of Technology

Pressures on Wage Decisions. By GEORGE P. SHULTZ. (New York: John Wiley and Sons, in conjunction with the Technology Press, Massachusetts Institute of Technology. 1951. Pp. 139 + vi. $3.)

Two major influences on wage decisions have been emphasized in recent literature on collective bargaining: economic pressures exerted by "impersonal market forces," particularly in the product market; and political pressures emerging from bargaining institutions and processes. Some observers have assumed that these themes are at odds with each other and require a choice between two competing "theories of wages." A more sensible view is that institutional and market influences interact through the medium of collective bargaining—offsetting, reinforcing, and modifying each other, and producing results which cannot be explained either by pure politics or pure economics. However, there has been a relative dearth of empirical studies testing this proposition and examining specific modes of interaction.

Mr. Shultz' monograph is a carefully documented study of wage determination in the Brockton, Massachusetts, shoe manufacturing district. His purpose

is to show "how these two views, market forces vs. human decisions, are synthesized when the total scope of collective bargaining relationships is examined."

In early chapters Shultz describes the characteristics of the Brockton shoe industry, the manufacturers' group and the Brotherhood of Shoe and Allied Craftsmen. The industry is highly competitive, and not very remunerative to either owners or workers; over the years there has been a movement into nonunion areas, and a distinct trend toward lower price lines. Fixed costs being small, labor cost is the focus of interfirm competition. Piece rates are prominent in the wage structure. The employers have strong goals in common, but the Brockton Shoe Manufacturers Association is limited in cohesiveness because its members concentrate on different grades of shoes and vary in their ability and inclination to take a strike. The Brotherhood, an independent union, consists of craft locals with considerable autonomy. There is pressure on officers from an active and impatient membership, and rivalry with a CIO organization in the shoe industry.

Noting that earlier writings on wage policy have dealt for the most part with general movements, Shultz identifies three types of wage decisions in the Brockton shoe district. First are general wage adjustments, which take the form of across-the-board percentage increases or decreases. These are strongly affected by pressure from dissatisfied members and comparison with rival union settlements. Second is the "grade system," under which labor costs are differentiated in accordance with selling prices. The system has been administered in an opportunistic fashion, grades being influenced by the financial position of the various producers. With the trend toward lower price lines, labor costs have not risen to the extent indicated by apparent general increases. Piece-rate adjustments make up the third type of wage decision. Piece rates are tightened or loosened in response to economic conditions, and like the grade system, "have provided a way in which the district has adjusted to circumstances not fully recognized in explicit across-the-board wage movements." In other words, in this piece-rate industry characterized by relatively high labor costs, low profits, and nonunion competition, the "employment effect" has an important impact on wages; but the impact is centered on the administration of the grade system and piece rates, rather than the negotiation of general adjustments.

Mr. Shultz concludes that neither producers nor workers are organized for an effective attack upon the economic problems of the district. "Thus," he notes, "the district's most important wage decision, how to organize within the firm for effective use of labor resources, is not made on a conscious level at all but simply results from many uncoordinated actions which, taken together, tend to aggravate rather than help solve the problem."

Pressures on Wage Decisions is not merely a superior case study of an interesting situation but an important contribution to theoretical understanding of wage determination under collective bargaining. We need more studies of this kind.

TITLES OF NEW BOOKS

Economic Theory; General Economics

HAJELA, P. D. *Keynes' general theory—trade cycle and foreign exchange.* (Allahabad: Pothishala Ltd. 1952. Pp. ii, 232. Rs.5/-.)

The three parts of this book of essays are almost independent of one another. The first part is an exposition of Keynes' *General Theory,* a commentary upon it and an appraisal of it. The second part is on the theory of foreign exchange—the purchasing power parity theories, balance of payments theory, and the theory of foreign exchange under a gold standard. The third part is on business cycle theory—the purely monetary, the monetary over investment, and Keynes' theory—and remedies for the cycle. There is a final chapter on the definition of money.

The Durban housing survey—a study of housing in a multi-racial community. Addl. rept. no. 2 of Natal Regional Survey by Research Sec., Dept. of Econ., Univ. of Natal. (Durban: Univ. of Natal Press. 1952. Pp. xii, 508. 35 *s.*)

Economic evaluation of federal water resource development projects. Report to the House Committee on Public Works from the Subcommittee to Study Civil Works, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 55.)

50 Years of reclamation: financial report to the nation's stockholders, 1902-1952. (Washington: Supt. Docs. 1952. Pp. 32.)

The flood control program of the Department of Agriculture, Report to the House Committee on Public Works by Mr. Jones of Alabama from the Subcommittee to Study Civil Works, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 43.)

Futures markets. Commodity Exchange act and Commodity Exchange Authority. Dept. of Agric. leaflet no. 330. (Washington: Supt. Docs. 1952. Pp. 12.)

Hells Canyon dam. Hearings before the Subcommittee on Irrigation and Reclamation of the House Committee on Interior and Insular Affairs, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 897.)

Materials survey: copper. Compiled for the Nat. Security Resources Board by the Dept. of the Interior, Bureau of Mines with the cooperation of the Geological Survey. (Washington: Supt. Docs. 1952. var. pp.)

New housing in metropolitan areas, 1949-51. BLS bull. no. 1115. (Washington: Supt. Docs. 1952. Pp. 64.)

Oil and Leasing act of 1920 with amendments and other laws relating to mineral lands. (Washington: Supt. Docs. 1952. Pp. 347.)

Petroleum productive capacity; a report on present and future supplies of oil and gas. Presented by the Committee on Oil and Gas Availability, Jan. 1952 to the Nat. Petroleum Council. (Washington: Nat. Petroleum Council. 1952. Pp. 102.)

A review of Commonwealth agriculture: production and trade. By the Commonwealth Economic Committee. (London: H. M. Stat. Office. 1952. Pp. 201.)

Supplemental report, Missouri River Basin agricultural program with letter from the Secretary of Agriculture, transmitting the report, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 217.)

Labor

BAERWALD, F. *Fundamentals of labor economics.* Rev. ed. (New York: Declan X. McMullen Co., distributors for Fordham Univ. Press. 1952. Pp. xvii, 480. $4.75.)

The first edition was reviewed in the June 1948 number of this *Review*. The present

edition has given careful attention to developments under the Labor-Management Labor Relations Act of 1947; the chapters on the theory and policies of full employment have been rewritten; and the Social Security Amendment of 1950 has been analyzed.

FLANDERS, A. *Trade unions.* Hutchins Univ. Lib. pub. (New York: Longmans, Green and Co. 1952. Pp. vii, 172. $2.25; text ed., $1.80.)

A textbook primarily with reference to the British labor movement.

PETERS, E. *Conciliation in action.* Principles and techniques. (New London: Nat. Foremen's Institute. 1952. Pp. xx, 266. $4.50.)

SHULTZ, G. P. and CRISARA, R. P. *The La Pointe Machine Tool Co. and United Steelworkers of America:* Case study no. 10 for NPA Com. on Causes of Indus. Peace under Collective Bargaining. (Washington: Nat. Planning Assoc. 1952. Pp. xiv, 81. $1.)

TOLLES, N. A. and RAIMON, R. L. *Sources of wage information: employer associations.* Vol. 3 in Cornell Stud. in Indus. and Labor Relations. (Ithaca: Cornell Univ. Press. 1952. Pp. xvi, 351. $3.)

Individual descriptions of 220 surveys of wages and related matters as conducted by 120 employer associations. There is also an analysis in general terms of the content of the surveys, and of the methods employed.

YODER, D. and WILSON, L. N. *Trends in personal ratios and salaries.* Reprint ser. no. 9, Indus. Relations Center, Univ. of Minn. (Minneapolis: Univ. of Minn. Press. 1952. Pp. 8. 75¢.)

Coal mine safety. Hearings before a subcommittee of the House Committee on Education and Labor, 82nd Cong., 2nd sess., on H.R. 268, a bill amending Public Law 49, 77th Cong., providing for the welfare of coal miners, Feb. 1952. (Washington: Supt. Docs. 1952. Pp. 491.)

Federal fact-finding boards and boards of inquiry, 1945-1951. BLS Works stoppages ser. 5, no. 1. (Washington: Bur. of Labor Statistics. 1952. Pp. 30.)

International Labour Office publications, Geneva, Switzerland.

Co-operative practice—an introduction. Stud. and rept. n.s. no. 32. Pp. 50. 50¢.
National employment services—Great Britain. Pp. xii, 189.
Yearbook of labor statistics 1951-52. 12th issue. Pp. xviii, 359. $5.
Minutes of the 112th session of the governing body, Geneva, June 1950. Pp. 215.

Interpreting the labor movement, Indus. Relations Research Assoc. pub. no. 9. (Champaign, Ill.: Twin City Printing Co. 1952. Pp. xi, 207. $3.)

Labor Arbitration Series, edited by G. W. Taylor, published for Wharton School of Finance and Commerce by Univ. of Pennsylvania Press (Price for entire series $10.):

BACKMAN, J. *Economic data utilized in wage arbitration.* 1952. pp. vii, 56. $1.
FREIDIN, J. *Labor arbitration and the courts.* 1952. Pp. vi, 58. $1.
HANDSAKER, M. and M. *The submission agreement in contract arbitration.* 1952. Pp. vii, 101. $1.50.
KENNEDY, VAN D. *Arbitration in the San Francisco hotel and restaurant industries.* 1952. Pp. vi, 113. $1.50.
KUHN, A. *Arbitration in transit—an evaluation of wage criteria.* 1952. Pp. xiii, 203. $3.
SIMKIN, W. E. *Acceptability as a factor in arbitration under an existing agreement.* 1952. Pp. vi, 67. $1.
SKILTON, R. H. *Industrial discipline and the arbitration process.* 1952. Pp. vi, 76. $1.
TRIPP, L. R. *Wage-reopening arbitration.* 1952. Pp. vi, 108. $1.50.
WITTE, E. E. *Historical survey of labor arbitration.* 1952. Pp. vi, 64. $1.

Labor recruitment for agriculture, the farm placement service, 1949, 1950, 1951; production, harvesting, processing. Prepared by the Bur. of Employment Security. (Washington: Supt. Docs. 1952. Pp. 32.)

National and emergency labor disputes. Hearings before the Senate Committee on Labor and Public Welfare and its Subcommittee on Labor and Labor Management Relations, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 767.)

The problem of delay in administering the Labor-Management Relations act. Staff report to the Subcommittee on Labor and Labor-Management Relations of the Senate Committee on Labor and Public Welfare, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 34.

Prolonged non-occupational illness—a nationwide study among employed persons. First Progress Report of the Research Council for Economic Security, pub. no. 95. (Chicago: Research Council for Economic Security. 1952. Pp. 23.)

Publications of the Subcommittee on Labor and Labor Management Relations—staff report to the subcommittee of the Senate Committee on Labor and Public Welfare, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 6.)

Population; Social Welfare and Living Standards

LAWRENCE, N. *Israel: Jewish population and immigration.* Bureau of Census, Internat. population stats. repts. P-90, no. 2, (Washington: Supt. Docs. 1952. Pp. v, 58. 30¢.)

Berekeningen omtrent de toekomstige loop der bevolking (The future development of the population in the Netherlands). Pub. of the Netherlands Central Bureau of Statistics. (Utrecht: W. de Haan. 1951. Pp. 99. *f* 6,60.)

Comparison of state unemployment insurance laws as of December 1951. By Bur. of Employment Security. (Washington: Supt. Docs. 1952. Pp. 123.)

Consumer problems in a period of international tension. An institute sponsored by Kansas State College and Consumers Union of the United States, June 1952. (Manhattan: Kansas State College. 1952. Pp. 84.)

Family income, expenditures, and savings in 10 cities. BLS no. 1065. (Washington: Supt. Docs. 1952. Pp. 110.)

Unclassified

BALLANTINE, J. W. *Formosa—a problem for United States foreign policy.* (Washington: The Brookings Inst. 1952. Pp. xi, 213. $2.75.)

NOTES

John H. Williams, of Harvard University, has been appointed chairman of the American Economic Association nominating committee for the current year. He would appreciate having suggestions for officers for next year at as early a date as possible. Such suggestions may be addressed to him at the Federal Reserve Bank of New York, 33 Liberty Street, New York, N.Y.

Retirements

The following members of the profession have been reported as retiring from teaching at the end of the current academic year:

Julius B. Bearnson, professor of economics, department of economics, College of Business, University of Utah.

Orval Bennett, professor of business and government at Washington University, St. Louis.

Pembroke H. Brown, professor of economics, University of Illinois.

Donald English, professor of accounting, Cornell University.

S. S. Huebner, professor of insurance, Wharton School, University of Pennsylvania.

Marion K. McKay, head of the department of economics, School of Business Administration, University of Pittsburgh.

Harry J. Ostlund, associate professor of accounting, School of Business Administration, University of Minnesota.

E. C. Stone, professor in the School of Business Administration, University of Pittsburgh.

Nina L. Youngs, instructor in accounting, School of Business Administration, University of Minnesota.

Visual Materials in Economics

A Visual Economics Laboratory was established at Columbia University in November 1951 and was financed for a year by a grant from the Alfred P. Sloan Foundation. Trustees of the Foundation have made an additional grant to cover the budget of the Laboratory until November 1953. Dr. Arthur Dahlberg is director of the Laboratory. The visual materials that are being prepared are in process of testing in courses in economics in Columbia College. Upon completion of the tests the entire output of the Laboratory will be made available to other colleges and universities. The material will probably be ready for distribution at the end of the current academic year.

Social Science Research Council Announcements

The Social Science Research Council announces a new program of stipends and fellowships designed to identify and assist able students at an early stage of their education. A grant from the Ford Foundation enables the Council to offer, during a period of three or four years beginning in 1953, Undergraduate Research Stipends which may be followed by First Year Graduate Study Fellowships. *Undergraduate Research Stipends* will be awarded to college juniors who will devote eight weeks or more during the summer between their junior and senior years to research under the guidance of designated faculty supervisors. Awards of *First Year Graduate Study Fellowships* will be made in the latter part of the senior year to about one-half of the undergraduate stipend holders who have shown superior promise of making successful careers in the scientific study of human behavior.

The Social Science Research Council also announces a Summer Institute in Mathematics for Social Scientists to be held at Dartmouth College, Hanover, New Hampshire, from June 22 to August 14, 1953. The Institute is open to faculty members and predoctoral and postdoctoral students who wish to improve their mathematical training. Holders of the bachelor's degree who are about to enter graduate schools may also be admitted. Enrollment will be limited to about thirty.

Deaths

Franz K. Balling died August 6, 1952.

Truman C. Bigham, chairman of graduate work and professor of economics, University of Florida, died December 29, 1952 in Dallas, Texas.

Frank Buchanan, U.S. Congressman, died April 27, 1951.

Clive Day, of Yale University, died July 27, 1951.

Elisha M. Friedman died March 25, 1951.

Ernest H. Hahne, of Miami University, Oxford, Ohio, died November 25, 1952.

Donald J. Hay, of the University of Illinois, died November 1, 1952.

Donald M. Marvin died April 1, 1952.

Arthur E. Murdoch died July 17, 1952.

Edwin F. Wendt died September 30, 1952.

William M. Whitten.

Appointments and Resignations

Stephen G. Allen, formerly of Stanford University, has joined the faculty of the University of Minnesota as assistant professor of statistics.

Clay J. Anderson has been granted a year's leave of absence from the Federal Reserve Bank of Philadelphia to serve as advisor to the Union Bank of Burma, Rangoon, Burma.

John W. Anderson, of Indiana University, has been appointed assistant professor of accounting in the College of Business Administration of the University of Georgia.

Werner Baer has joined the staff of Bache & Company, members of the New York Stock Exchange, as security analyst. He continues to teach economics in the School of General Studies at Hunter College.

C. Kenneth Beach, of the School of Industrial and Labor Relations, Cornell University, has been granted a leave of absence to serve as coordinator of training activities for Arabian American Oil Company.

Richard F. Behrendt is chief of the United Nations Technical Assistance Mission to Paraguay and advisor to Paraguay's National Planning Commission for Economic Development. He will occupy a new chair for sociology and international economics at the University of Bern, Switzerland, in the fall of 1953.

Russell Bowers, formerly professor of accounting at the University of Georgia, has been appointed lecturer in business administration in the School of Business Administration, Emory University.

John W. Bowyer, Jr., has been appointed assistant professor of finance in the School of Business and Public Administration of Washington University, St. Louis.

Edward C. Budd has been promoted from instructor to assistant professor of economics at Yale University.

David W. Bussell has resumed teaching at the Ohio State University after having been in active service in the U.S. Navy for one and one-half years.

J. Carl Cabe has been appointed assistant professor of economics at the University of Kansas.

Arthur E. Carlson has been appointed assistant professor of management in the School of Business and Public Administration of Washington University, St. Louis.

William T. Chaffin has resigned as assistant professor of accounting in the College of Business Administration of the University of Tennessee.

Ralph J. Chances has been appointed assistant professor of economics in the College of Business Administration, Tulane University.

Wen-yu Cheng has been promoted to assistant professor of economics at Marietta College.

M. Gardner Clark, of the New York State School of Industrial and Labor Relations, Cornell University, is in Milan making a study of labor problems in the Italian metal industries under a Fulbright grant.

Neil Corothers, dean emeritus, Lehigh University, has returned from Korea, where he has been on special assignment as general economist, United Nations Civil Assistance Command, Eighth Army, and personal adviser to the Commanding General, Civil Affairs, Korea.

Wilfrid H. Crook is on leave of absence from Colgate University to do further research on the general strike, under the auspices of the Social Science Research Council.

Ben F. Curry was lecturer in labor economics at the University of North Carolina in the winter quarter.

A. M. Dreyer has been promoted from assistant professor to associate professor of economics at the University of South Dakota.

Otto H. Ehrlich has been promoted to associate professor of economics at the Graduate School of Arts and Science of New York University.

Emanuel R. Fuchs has been appointed staff economist to the Department of Interior's Missouri Basin Field Committee.

Paul R. Gawthrop has been promoted to assistant professor of economics and business administration and acting head of the department at Marietta College.

Victor Gerdes, of the University of Wisconsin, has been appointed assistant professor of economics at Beloit College.

Frank F. Gilmore has been appointed associate professor of management in the School of Business and Public Administration, Washington University, St. Louis.

Paul N. Guthrie has been on leave from the University of North Carolina in the fall and winter quarters to serve first as a public member of the Wage Stabilization Board and then as the President's representative in the handling of wage matters involving the railroad system of the country.

Challis A. Hall has been promoted from assistant professor to associate professor of economics at Yale University.

Morrison Handsaker, of Lafayette College, is on leave this semester to act as consultant on labor relations, in Germany, under a grant from the Department of State.

Rector R. Hardin, formerly of Howard College, has been appointed professor of economics in the College of Business Administration of the University of Georgia.

Franciscius Harrison, of Western Reserve University, is visiting associate professor of management at the Ohio State University during the winter and spring quarters of 1953.

Samuel P. Hayes, Jr., has returned to Washington to be assistant director of the Mutual Security Agency, in charge of Far East programs, after spending a year in Djakarta as chief of the ECA-MSA Special Technical and Economic Mission to Indonesia.

Harold J. Heck, of Tulane University, received a Fulbright grant to lecture in the 1952-53 school year at Waseda University in Tokyo, Japan.

Richard L. Hitchcock has been appointed assistant professor of economics at the University of Louisville.

Harvey W. Huegy has returned to teaching at the University of Illinois after serving the Irish Free State as consultant on export problems.

M. J. Jucius, of the Ohio State University, is in Turin, Italy, lecturing in the School of Commerce and Engineering, University of Turin and in the Institute of Technology, under the sponsorship of the National Management Council of the United States and the Turin Manufacturers Association.

E. A. Kincaid has been appointed associate chairman of the McIntire School of Business Administration of the University of Virginia.

Frank H. H. King, formerly of the New Mexico Military Institute, has accepted an appointment as lecturer in economics at the University of Hong Kong.

Milton R. Konvitz, of the New York State School of Industrial and Labor Relations, Cornell University, taught at the Salzburg Seminar last fall and is now engaged in research under a fellowship award of the Fund for Advancement of Education.

Richard Landry has been promoted to associate professor and head of the department of economics and business administration of St. Lawrence University.

James H. Lemly, of Indiana University, has been appointed assistant professor in the College of Business Administration of the University of Georgia.

Richard W. Lindholm has been granted leave from Michigan State College to help organize a department of economics in the university being established at Karachi, Pakistan and to work with the State Bank of Pakistan.

Elmer P. Lotshaw has been appointed assistant professor of finance in the School of Business and Public Administration of Washington University, St. Louis.

Friedrich A. Lutz has resigned from Princeton University to accept a professorship in economics at the University of Zurich, Switzerland.

Arthur Mandel, formerly of the University of California at Los Angeles, is now attached to the 5th Air Force Headquarters in Seoul, teaching economics in the Far Eastern Teaching Program of the University of California.

Donald J. May has been promoted to assistant professor of economics in the School of Business Administration of Emory University.

Lester B. McAllister, Jr., of the University of Oregon, has been appointed assistant professor of economics at Beloit College.

David C. Melnicoff has resigned as business economist for the Federal Reserve Bank of Philadelphia and has accepted a position as assistant to the general manager of the Penn Fruit Company of Philadelphia.

Chester A. Morgan has been appointed assistant professor of labor and industrial management at the State University of Iowa.

Mary E. Murphy, of Los Angeles State College of Applied Arts and Sciences, has been awarded a Fulbright grant to lecture at Queensland University, Brisbane, Australia, in 1953-54.

John A. Nordin has been promoted to professor of economics at the Iowa State College.

Oscar Ornati has been appointed assistant professor in the New York State School of Industrial and Labor Relations, Cornell University, effective in July.

George S. Peck has been appointed assistant professor of money and banking at the State University of Iowa.

Mark Perlman has been appointed assistant professor in the New York State School of Industrial and Labor Relations, Cornell University.

Arthur L. Rayhawk, formerly with the Defense Production Administration, has been appointed professor of business administration and director of the Bureau of Business Research, University of Georgia.

Marshall A. Robinson has returned to his duties as assistant professor of economics at Tulane University after a year's leave of absence with the National Bureau of Economic Research.

John H. Roseboom has resigned from Indiana University to accept an appointment as statistician in the Quality Control Division of the U.S. Air Force at Wright Patterson Field.

Edward H. Sargent, Jr., is assistant professor in the New York State School of Industrial and Labor Relations, Cornell University.

Alfred L. Seelye, of the University of Texas, has accepted an appointment to teach at an Executive Training Institute, Turin, Italy, from December 1952 to June 1953.

Lewis Severson will be lecturer in Canberra University College, Canberra, Australia during the 1953-54 academic year under a Fulbright award.

Leonard S. Silk, after a year spent in research in Norway under a Fulbright grant, is now serving as economic analyst on the staff of the Special Representative in Europe, with headquarters in Paris.

Adolf Sturmthal, of Bard College, is visiting professor at the New York State School of Industrial and Labor Relations, Cornell University, in the current academic year.

Theodore A. Sumberg has accepted a short-term appointment as statistical advisor to the Mutual Security Agency Mission to China, Taipei, Formosa.

John D. Sumner has returned to the University of Buffalo after spending a year and a half as economic advisor in the China Mission of the Mutual Security Administration at Taipei, Formosa.

Daniel L. Sweeney has been appointed assistant professor of accounting at the State University of Iowa.

Arthur R. Upgren is on leave from the University of Minnesota in the winter and spring quarters on a Fulbright fellowship for travel, lecturing and studying in Europe, particularly Denmark.

Rutledge Vining has been appointed acting chairman of the McIntire School of Business Administration at the University of Virginia.

Porter S. Wood, of Marshall College, has been appointed assistant professor of accounting in the College of Business Administration of the University of Georgia.

Dallas M. Young, associate professor of economics at Western Reserve University, has been appointed acting chairman of the regional Wage Stabilization Board for Ohio and Kentucky.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Sales economist and sales management: Would like to employ men of outstanding intellectual ability who have good background in economics and sales psychology with the ability of making the customer want to buy. Must be of highest caliber with the ability to perform liaison with state and civic officials. Car necessary. Under 30, free to travel, interested in $20,000 to $25,000 earnings. Expanding company; leader in its field; has openings in a number of states. Write full details to H. D. Umstott, Vice President, National Headquarters, 2701 14th Street, N.W., Washington 9, D.C.

Economic analyst: Distinguished national organization operating primarily in economic study field desires economic analyst with a background in economics and writing ability, preferably in late twenties or early thirties. Probable location Washington, D.C. Give education, job experience, salary record. Replies will be held in strict confidence. P155

Economics, finance: Wanted a teacher for economics and finance; Ph.D. preferred; salary and rank depending upon training and experience. Begin September, 1953. Write Dr. Herman P. Thomas, Chairman, Department of Economics, University of Richmond, Virginia.

Marketing and management: A Southern university will have an opening in September, 1953, for a young man with a Ph.D., to handle courses in the areas of marketing and management, calling for the rank of instructor or assistant professor. Selection of courses can be adjusted. Salary is open. P156

Marketing: Midwestern university wants man for one-year assignment only, to teach marketing, advertising, and sales. This is a temporary appointment to replace a man who is to study for his doctorate. Position open as of September, 1953. P157

Economists Available for Positions

Personnel administration, labor relations, banking, theory: Man, 36, married. Experienced teacher or administration; 12 years of experience in leading universities and business firms. Research, publications, government, and business consultant. E194

Economics and business administration: Man, 49, B.S. (agricultural economics), M.A., and near Ph.D. (marketing). Seventeen years of college and university teaching; extensive business and commercial experience; over 4 years as government economist or business analyst. Available immediately, preferably Pacific Northwest. E239

Money and banking, fiscal policy, business cycles, international economics, investments: Man, 38, married, Ph.D. Experience as a newspaperman and 5 years of teaching experience. Desires research or teaching position. E263

Labor economics, industrial and labor relations, labor law, personnel administration, economic principles: Man, 27, B.A. (*cum laude*); M.B.A. (industrial relations and personnel administration), LL.B., New York University. Teaching experience; 3 years of experience in collective bargaining negotiations, preparing and arguing arbitration cases, administering health and welfare plan; thorough knowledge of NLRB procedures and WSB and SSB regulations. Available now for teaching or research. E270

Economic analysis, business cycles, public finance, money and banking, national income, international economics, statistics: Man, 34, married, Ph.D. residence completed. Seven years as economist-writer with research and investment organization; brief teaching experience; research in Middle East conomy. Seeks research, writing, or teaching position, West Coast preferred. E278

Economic principles, theory, history of economic thought, American economic and financial history, security markets, corporation finance, labor and allied subjects: Man, 39, married, B.S. (*magna cum laude*), 1949, M.A., 1950, all examinations and course requirements toward Ph.D. completed and expects to finish dissertation at New York University by June, 1953. Now on teaching staff of Eastern college. Seeks teaching position starting September, 1953. E318

Economics, business law, marketing, retailing, labor relations, labor law, labor economics: Man, 40, B.S., 3 years of law, completing thesis for LL.D., June, 1953, at European university. Seven years of university teaching; 4 years of industrial experience; 10 years of business experience. Available after June, 1953. E336

Money and banking, business cycles, theory of statistics, business statistics, economic theory, history of economic thought, economic history, international economics: Man, 31; Ph.D. Brief teaching and substantial research experience. Desires teaching and/or research position. Available in September, 1953. E382

International trade, corporation finance, investments, economic theory, history of economic thought, management, accounting: Man, 30, M.S. (management), M.A. (economics), Ph.D. expected in June, 1953, University of Illinois. Brief experience in teaching; 5 years in foreign trade and business administration. Available for academic or nonacademic appointment in September, 1953. E414

Economic analysis, public finance, foreign trade, money and banking, statistics, U. S. economic history, economic geography, personnel: Woman, 29, M.A., Columbia University. Four years of experience as research-administrative assistant. Available immediately. E418

Labor, history of economic thought, elementary economics, public finance: Man, 32, married, Ph.D. Four years as instructor in Big Ten university. Now employed by government agency and as assistant professor at a large Ohio university. Research experience and publications. Desires teaching position or job with research and writing opportunity. Available in fall, 1953, or January, 1954. E419

Air transportation, international economics, international organization, history of economic thought, economic history, contemporary economic theory, public finance: Man, 32, B.A., M.A., Ph.D. in economics; 11 years of economic research in several areas of the federal government, including national income, fiscal policy, international economics, and air transportation; currently employed as economist in one of the aviation agencies of the federal government. Desires a teaching position in economics. E420

Statistics, economics, organization and administration: Man, 34, married. Teaching and practical experience and command of several languages; seeks position as teacher, economist, or research worker. E421

Transportation, public utilities, business and government, insurance, economic history, theory, other economics and business: Man, 33, married, M.B.A., Ph.D., California. University teaching; government economist; some business experience. Desires permanent teaching and/or research position. Available in spring or fall of 1953. Roy J. Sampson, Box 304, Route 1, Forest Grove, Oregon.

International economics, money and credit, principles, Far Eastern economics, public finance, business cycles, price and income analysis, economics of mobilization, economic theory and its history: Man, 30, married, B.A., M.S., all course requirements for Ph.D. Five years of teaching; 3 years as assistant professor and division head, Western state college. Chief economist, territorial office, stabilization agency, since July, 1951. Seeking teaching, research, or combination. Available in spring, summer, or fall semesters, 1953. E422

Principles, economic history and institutions, government and business, structure of the American economy, economics of industry, regional planning, comparative economic systems: Man, 29, will receive Ph.D. in January, 1953. Four years of teaching experience and 2 of research. Desires teaching position. Prefers West Coast but will consider any location. Available in June or September, 1953. E425

Transportation, U. S. economic history, labor economics, political economy: Man, 32, B.A. (economics), M.A. in Education, Yale, M.A. (economics), LL.B., Boston, Ph.D. residence requirements completed. Experience in teaching, research, and writing. Seeks teaching or research position. E428

Labor problems, trade unionism, economic principles, economic analysis, social security, money and banking: Man, 29, married, Ph.D. residence and written examinations completed. Teaching experience at two large New York universities. Now employed by federal government. Desires teaching position. Available immediately. E429

Corporation finance, money and banking, accounting, consumer and real estate finance, investments: Man, 41, married, Ph.D. in finance and C.P.A. Extensive research experience with government agencies, Federal Reserve Bank, and a private research organization; 8 years of undergraduate and 3 of graduate teaching; numerous publications. Currently in an administrative capacity with a research organization. Desires to return to teaching. Available in September, 1953. E432

Labor, comparative economic systems, current economic problems, economic history, economic and social thought, money and banking, public finance, international trade, personnel and manpower policy: Man, 37, married, M.A., and Ph.D. residence completed at Columbia University. Six years of teaching economics and social science as well as background in adult education; 3 years as editor and research director in the book publishing and public relations field dealing with labor relations; 3 years of personnel and industrial relations work in industry; market and opinion research experience. Interested in teaching, research, writing, editorial and/or administrative positions. E434

Agricultural economics, economic geography, economic analysis, international relations, international administration, foreign area specialist (Eastern Europe, Far East, Pacific Area): Man, 34, married, B.S., Cornell (agricultural economics); working on graduate thesis in underdeveloped area development, American University. Three years in private industry, including 1 year private international organization; 6 years with federal government, presently employed in Washington, D.C. Strong sales background. Interested in administrative or research position, government or private industry; will consider outstanding sales position, particularly export-import field. Willing to relocate; particularly interested in Mountain States or far West. E435

Economic principles, business cycles, public utilities, transportation: Man, Ph.D., California. Broad experience in teaching and as economist with nationally known corporation. Available in September, 1953. E436

Economic analysis, business cycles, labor economics, fiscal policy, money and banking, history of economic thought, statistics: Man, 34, married, A.B., M.A., Ph.D., from a large Eastern university (*magna cum laude*). Two years of experience in economic research and accounting in a large corporation; 4 years of experience in theoretical economic research in the federal government; publications. Desires a position somewhere in the West in fields of economic research, industrial relations, marketing, or teaching. Available immediately. E437

Industrial management, labor relations, personnel management: Man, 39, married, Ph.D., Midwestern state university. Academic and business experience. Supplementary areas of interest and research are industrial supervision and management theory. Desires academic responsibility for one of the listed areas. Available in summer or fall, 1953. E438

Labor law, business law, public control of business, etc.: Man, Ph.D., LL.B., associate professor. Position wanted for summer, 1953. E439

International trade, resources, finance, economic principles, etc.: Man, 33, married, B.S. (management), M.B.A. (foreign trade); will receive Ph.D. in June, 1953. Five years of university teaching; 1 year of foreign service (international negotiation); several years of industrial and commercial experience. Desires teaching-research post, with desirable climate and topography. Available in September, 1953. E440

Economic analysis, international economics, labor economics, housing, money and banking, business cycles, theory and history of ideas: Man, 35, married, Ph.D. Five years of teaching experience; 4 years of research in federal government and abroad on Fulbright and other fellowships; presently with European Office, Mutual Security Agency. Desires teaching or research position. E441

Industrial organization and control, economic principles and theory, labor economics, money and banking, theory of business, marketing, business organization and management policy: Man, 34, married, B.A., Penn State; M.A., California; Ph.D., Harvard, dissertation half completed. Five years of teaching experience; 2 years of research experience; 1 year as government economist. Currently at West Coast university conducting specialized course for industry. Desires teaching or research position in economics or business administration. Available in September, 1953. E442

Economic principles, commercial law, history of economic thought: Man, 33, married, B.A., 1950, M.A., Duke, 1952, plus 1 year of course work toward Ph.D. Six years of clerical experience in foreign banking; now teaching at Southern college. Seeks teaching position starting in September, 1953. E443

Principles of economics, labor problems, statistics, the economy of Japan: Woman, 34, Ph.D. World travel; 7 years of successful college teaching. Prefers Northeastern or Midwestern location. Available in summer, 1953. E444

International trade, marketing, industry studies, economics of military government: Man, 35, married, B.A., Southern Methodist University, M.A., 1952; certificates from Industrial College of the Armed Forces and Armed Forces Information School. Three years of marketing and distribution; 2 years of management consulting; 3 years of teaching in Military Government School. Accomplished public speaker. Seeks position as educational director of trade organization, administrative officer of bureau of business research, and/or liaison and sales promotion. E445

Economic theory, international economics, money and banking, history of economic thought, statistics, mathematics for economists: Man, 28, M.A., all examinations and course requirement toward Ph.D. completed and expects to finish dissertation at the University of Chicago by summer, 1953. Seeks research or teaching position. E446

Theory, systems, international economics, economic history, history of economic thought, social control: Man, 34, Ph.D., Columbia. Formerly associate professor at Eastern college; now in responsible government position; publications. Seeks academic post. E447

International economics, money and banking, labor economics, industrial management, economic theory, history of economic thought: Man, 28, M.A. in Economics, Ph.D. expected in August, 1953, University of Illinois. Brief experience in teaching, research, and foreign trade administration. Available for academic or nonacademic position in September, 1953. E448

Social control of business, business law, labor, economic principles, business administration: Man, 26, M.A., J.D., Ph.D. candidate, outstanding record. Books; 6 years of teaching experience in leading institutions at graduate and undergraduate levels; stimulating teacher; interested in writing; excellent references. Faculty member at leading private university. Desires academic or nonacademic employment for summer, 1953; also will consider transfer to top-notch liberal arts college. Interested in opportunities for foreign travel. E449

Labor economics, personnel management, industrial sociology, comparative economic systems, market research: Man, 35, Ph.D. expected in spring, 1953. Seven years of teaching experience; at present head of small economics and sociology department; several years of industrial, market, opinion survey experience; project director of research foundation. Multilinguist; extensive foreign travel and research. Interested in teaching and/or research position. E450

Economic development, public finance, international and regional economics, monetary economics, U. S. economic history, statistics: Man, 33, married, Ph.D., Columbia University. Five years of teaching experience; 2 years as consultant in economic development to territorial government; research, writing, and business experience; foreign work and travel. Available for teaching, research, or nonacademic position. E451

Economic fluctuations, economic system of Soviet Union, economic demography, with special consideration of problem of migrations: Man, 32, doctor in economics at an outstanding European university; 1 year of supplementary study at an outstanding American university. Author of a book. Desires employment as instructor or research worker. E452

Finance, international economics, statistics, accounting, economic geography: Man, 41, married, B.S. (business administration), M.A. (education), Ph.D. (economics). Now serving as statistician for leading petroleum company. Ten years of college and university teaching, with consulting and publications. Seeks university position. Available in September, 1953. E453

Comparative economic systems, history of economic thought, international trade, economic theory, money and banking, principles of economics: Man, 26, A.B., Indiana University; M.A., Columbia University; now completing Ph.D. residence requirements at Western university. One year of teaching experience. Seeks position at Eastern college or university. Available in September, 1953. E454

Labor, principles, elementary statistics, international economics, theory, history of economic thought, comparative economic systems: Man, 26, B.A., M.A., Ph.D. residence requirements completed and dissertation nearing completion. One and one-half years of teaching experience; 2 years as research fellow in industrial relations institute; 1 year as industrial relations analyst with Wage Stabilization Board. Three published articles. Currently part-time instructor in Eastern university. Seeks teaching post or position with industrial relations institute. Available in September, 1953. E455

American economic history, corporation finance, business cycles, economic theory, statistics, economic principles: Man, 27, married, B.A., New York University; M.A., Columbia University; mechanical engineering training, Polytechnic Institute of Brooklyn. Seeks part-time evening position teaching at a college in the New York metropolitan area. E456

Marketing research analysis: Above young man also seeks marketing research analyst position with a consulting engineering firm in the New York area to combine his educational training with his experience as a Social Science Analyst for the Bureau of the Census and marketing director for the Israel Bond Drive in Nassau County. Contacts in both industry and government. Excellent references available upon request from the Placement Office at Columbia University. E456

"Hello, Mother! It's Me!"

"Thought I'd call you up and find out if you arrived OK.

"No, it didn't take long. Seemed like I'd just given the operator the number when I heard your voice.

"Good thing I remembered to jot down Aunt Sue's number when you were there the last time."

YOU'LL FIND THIS IS A GOOD IDEA FOR YOU, TOO...

Call By Number

You save time on out-of-town calls when you give the Long Distance operator the number you want.

So here's a helpful hint. Write down the out-of-town numbers you already know. If there's a new number you don't have—or an old one you've forgotten—be sure to add it to the list when the operator gives it to you.

The Bell Telephone Company in your community will gladly give you a free Telephone Numbers Booklet.

SOME NOTES ON MULTIPLIER THEORY

By RALPH TURVEY[1]

The theory of the multiplier may be viewed in either of two ways. It may be regarded as the specification of a set of relationships which the econometrist is to measure, or alternatively as of purely qualitative significance, its purpose being to explain one aspect of the determination of national income. In the latter case its function is to display the relevance and *modus operandi* of various factors.

In either context, the tendency in recent writings has been to develop a less aggregative approach as, for example, in the discussion of matrix multipliers. The present article is intended as a further contribution in this direction, but it aims at synthesis as well as innovation.

The first section restates the static theory for an economy with a government and with foreign trade, and in order to achieve consistency with the social accounting approach makes a sharp distinction between firms and households. This involves a clear separation of business saving from personal saving, a good example of useful "disaggregation." Section II analyses the effects on national income of changes in government spending and taxation without being confined to one type of tax and one type of spending. It is shown that the theorem that a balanced budget-increase has a multiplier of unity is a very special case. Section III, which uses a pure Stockholm School approach, demonstrates how the relationship between saving and investment *ex post* and *ex ante* can only be understood if, consonantly with the division between households and firms, the markets for factors and for goods are distinguished. It is also shown that since saving (*i.e.*, not-spending) is a derived concept, analysis in terms of spending is preferable because of its directness.

[1] The author is reader in economics at the London School of Economics, University of London.

I. *The Static Multiplier*

The multiplier analysis of the determination of the level of national income is essentially a special case of general equilibrium theory, differing from it in respect of a number of simplifying assumptions.[2] For the purpose of this paper, the main assumptions may be given the following form:

1. Groups of economic units are consolidated into sectors which are treated as units, *i.e.*, the analysis is macro-economic.[3]
2. Only income effects enter into the behaviour equations.
3. Certain magnitudes, such as investment, are autonomously determined.
4. The supply curves of all newly produced goods and of factor services are infinitely elastic; thus no distinction is made between the real and money values of the variables.

The analysis is, to start with, in terms of comparative statics and relates to the short period, though one aspect of growth economics is briefly mentioned.

The simplest way of describing the system is to list the transactions which enter into the analysis, as in the table below. Since this table is largely self-explanatory, little need be said about it. Items not shown, such as profits tax and wage payments by government are assumed to be zero. Indirect Taxes (and Subsidies) are on consumer goods only,

Paying Sector / Receiving Sector	Firms	Households	Government	Rest of the World
Firms	Interfirm transactions in intermediate & capital goods	Consumption (at market value)	Government Purchases Subsidies	Exports
Households	Factor Purchase (=Factor Sale)		Transfers	
Government	Indirect Taxation	Income Tax		
Rest of the World	Imports			

[2] Compare Burgess Cameron's derivation of the Leontief system from general equilibrium theory. "The Construction of the Leontief System," *Rev. Econ. Stud.* (1950-51), XIX (1), 19-27.

[3] Richard M. Goodwin "The Multiplier as Matrix," *Econ. Jour.* (Dec. 1949), LIX, 537-55 and John S. Chipman, *The Theory of Intersectoral Money Flows and Income Formation* (Baltimore, 1951) provide a formal analysis of *n* sector models.

and are paid (received) by Firms which are also assumed to handle all Imports. The term Factor Purchase is used to include all income payments by Firms to Households: wages, salaries, rent, interest and dividends.

Neither National Income nor Investment[4] is shown explicitly, the former because it is a derived concept, and the latter because it consists of several components, one of which, physical increases in Firms' stocks of their own products valued at market price, is only a payment flow to the extent of the necessary Factor Purchase. Investment being that part of the national output not sold by Firms to other sectors, the relationship between it and National Income is given by the following identity:

Y	≡	I	+	G	+	E	+	C	+	L	−	K	−	M (1)
National Income (output) at factor cost		Investment		Government Purchases		Exports		Consumption		Subsidies		Indirect Taxation		Imports

National Income exceeds the wages, salaries, rent, interest and dividends received by Households (Factor Sale = Factor Purchase) by the amount of gross business saving.[5] The Disposable Income of Households is related to their Factor Sale as follows:

D	≡	F	+	T	−	U	(2)
Disposable Income		Factor Sale (Purchase)		Transfers		Income Tax	

In order to explain the determination of National Income it is now necessary to specify the "spending functions" of the various sectors:

Rest of the World

The value of Exports (E) is taken to be exogenously determined.

Government

Government Purchases (G) of newly produced goods from Firms is assumed to be constant. Subsidies and Transfers are dealt with below.

Households

C	=	α_3	+	$h \cdot D$	(3)
Consumption at market value		constant term		Households' Disposable Income	

[4] Both of which are taken gross throughout.

[5] Plus corporate taxation. This is assumed to be zero in this section of the paper.

h is the marginal propensity of Housholds to consume with respect to their Disposable Income.

$$\underset{\text{Income Tax}}{U} - \underset{\text{Transfers}}{T} = \underset{\text{constant term}}{\alpha_4} + \underset{\text{Factor Sale}}{t \cdot F} \tag{4}$$

where t is the marginal rate of Income Tax net of Transfers. The constant term will be negative, since at low income levels Transfers will exceed Income Tax and at high income levels Income Tax will exceed Transfers which may fall as Factor Sales and employment rise.

Firms

Firms pay Indirect Tax and receive Subsidies on their sales of consumer goods. Assuming proportionality:

$$\underset{\text{Indirect Taxation}}{K} - \underset{\text{Subsidies}}{L} = \underset{\text{Consumption at market value}}{k \cdot C} \tag{5}$$

k is the marginal (and average) rate of Indirect Taxation minus Subsidies expressed as a fraction of Consumption at market value.

This, and equations (3) and (4) involve an aggregation problem. Thus a simple relation between Consumption and the Disposable Income of Households requires either that changes in the distribution of the latter have no effect on Consumption (all Households have the same h) or that the distribution is a function of the level of Disposable Income.

The aggregation of all firms into one sector is more complicated, because they not only make purchases from other sectors but also purchase capital goods and intermediate goods (materials) from one another. Consider first a single firm. Apart from Indirect Taxes, its purchases (payments) may be listed as follows:

(a) Intermediate goods from other firms or the rest of the world. Some of these purchases will vary with output while others, *e.g.*, purchase of fuel for heating and stationery for the office, will be overheads. In addition a firm may invest by increasing its stocks of intermediate goods.

(b) Capital goods from other firms or the rest of the world. Given both the total investment of the firm and its composition, this item will be constant.

(c) Rent and interest paid to Households. The analysis being short-term, these overheads are assumed constant.

(d) Wages and salaries paid to Households, whether overheads such as payments for management and research (assumed constant) or variable labour cost.

(e) Dividends paid to Households. These depend upon profits which, given (a) to (d) above, are a function of sales.

The investment carried out by a firm consists of three components: purchase of newly produced capital goods,[6] purchase of intermediate goods for stock and increase in stocks of its own product, this last component being the difference between output and sales. The items (a) to (e) above can all be taken to be functions of Sales + Investment on the assumption that the composition as well as the magnitude of Investment is constant. Thus the Factor Purchase, Import Purchase and Purchase of Goods from other firms of any firm are functions of the sum of the Sales of its product and its Investment.

The aggregation problem[7] consists of deriving from all these functions two functions relating aggregate Imports and aggregate Factor Purchase to the sum of aggregate Investment and aggregate Sales (by all firms together) of newly produced goods to all other sectors. Assuming linearity[8] the two functions can be written:

$$\underset{\text{Imports}}{M} = j\cdot(\underset{\text{Investment}}{I} + \underset{\substack{\text{Government}\\\text{Purchases}}}{G} + \underset{\text{Exports}}{E} + \underset{\substack{\text{Consumption}\\\text{at factor}\\\text{cost}}}{C-K+L}) \tag{6}$$

$$\underset{\substack{\text{Factor}\\\text{Purchase}}}{F} = \underset{\substack{\text{constant}\\\text{term}}}{\alpha_7} + b\cdot(I + G + E + C-K+L) \tag{7}$$

The constant term is equal to overheads (other than depreciation) plus any constant term in the dividend payment function. The significance

[6] From the point of view of the individual firm purchases minus sales of second-hand capital goods should be included, but for the economy as a whole these items cancel out.

[7] It may well be that the aggregate functions are derivable only on the assumption that all firms are identical, *i.e.*, in a one-commodity world. Certainly it will not do to assume that the proportional composition of final output and of the inputs of each separate firm is invariant with respect to the level of output, for that would be inconsistent (a) with the treatment of some inputs as overheads which are fixed in the short run and (b) with the assumption that I, G and E are given.

Goodwin maintains (*op. cit.* pp. 541-43) that the Keynesian system implicitly assumes that the marginal propensity to save of all firms is zero so that if output increases by x total Factor Purchase will increase by x whatever the composition of the increase in output. (This relates to a closed economy.) He rightly says that this procedure has the disadvantage of ignoring "the phenomena of internal financing, of the failure to disburse earnings, of heavy fixed charges and of the payment of dividends above current earnings" (p. 543).

[8] Even if this is not an approximation there is the additional complication that straight-line relationships may be kinked. It is reasonable, for example, to assume that dividends equal half net profits, but unreasonable to suppose that when net losses are being made shareholders will pay money to their firm!

of b and j can best be illustrated by an example: Suppose that when output and sales rise by £100 an additional £50 must be spent on labour and £10 on imported raw materials and that of the £40 increase in profit half is paid out as additional dividends. Then $b = 0 \cdot 7$ and $j = 0 \cdot 1$. It will be seen that $(1 - b - j)$ is the marginal propensity of firms to save with respect to (Investment + Sale of Goods to other sectors).[9] $(b + j)$ is not the marginal cost of final output to the sector of Firms, since it refers to money value not to quantity. It is not even the marginal cost of £1 worth of output, since it includes marginal dividend payments and the import of finished goods as well as materials.

Solution of the seven equations for National Income (Y) gives:

$$Y = \frac{I + G + E + (1 - k)\ [\alpha_3 + h \cdot \{-\alpha_4 + (1 - t) \cdot \alpha_7\}]}{1 - b \cdot (1 - t) \cdot h \cdot (1 - k)} (1 - j) \qquad (8)$$

The numerator, the multiplicand, consists of the "injections" Investment, Government Purchases and Exports together with the invariant part of Consumption (at factor cost) due to the constant terms in the Consumption, Tax-transfer and Factor Purchase functions—all multiplied by $(1 - j)$ to remove the import content.

The denominator can be explained as follows: Of an increase in Investment or Sale of Goods, b is paid to Households and t of this is taken in Income Tax. Households spend h of what is left on Consumption, the value at factor cost being $(1 - k)$ of this.

A geometrical version of the multiplier is given in Figure 1 where the dashed lines show the equilibrium position. The N.E. quadrant shows Consumption at market value as a function of Disposable Income (3)[10] and Indirect Taxation minus Subsidies as a function of Consumption expenditure (5). The N.W. quadrant adds Consumption at factor cost to Investment, Exports and Government Purchases (1). The S.W. quadrant shows their sum as determining Factor Purchase and Imports (7) and (6). The S.E. quadrant relates Disposable Income to Factor Sale (2) and (4).

The multiplier formula given above (8) differs from the more customary ones in that, consonantly with the clear division of the economy into sectors, the functions relating Factor Purchase to total spending and Consumption to Disposable Income are sharply distinguished instead of being lumped together into one consumption function, the orthodox consumption function, which fails to distinguish Firms behaviour from Household behaviour. The relationship of the

[9] Equals National Income plus Imports.

[10] The figures in brackets refer to the numbers of the equations.

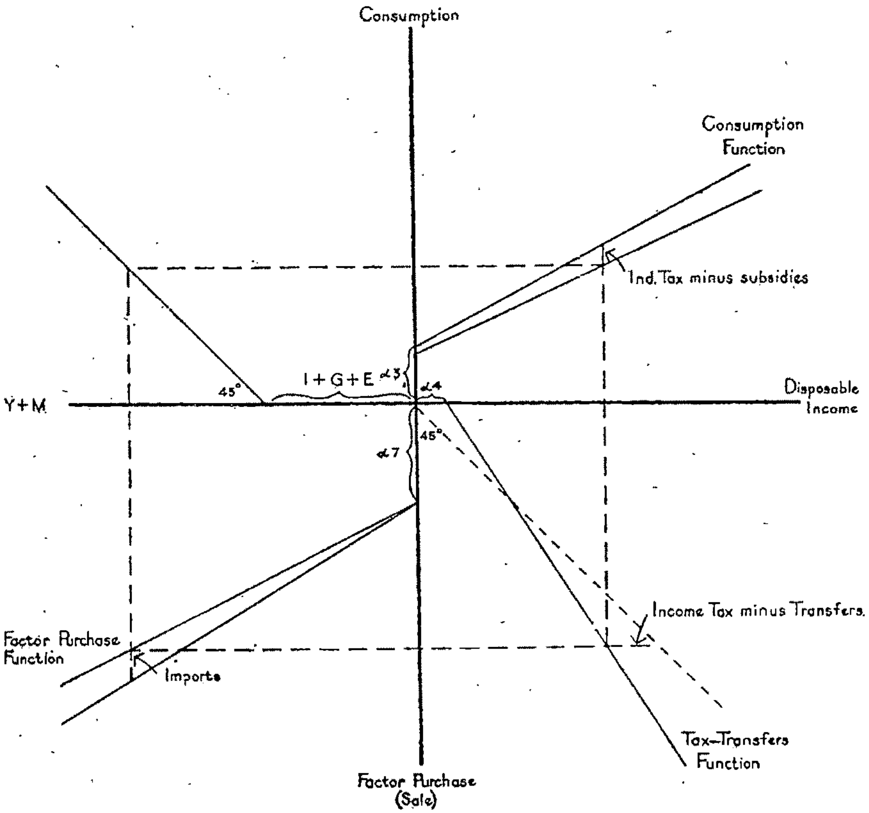

FIGURE 1

aggregative functions to the decision-making of individual economic units is made clear and there is no danger of forgetting business saving in discussing the relation of Consumption to National Income.

The advantage of the distinction is apparent even when, as in the present analysis, only income effects are considered.[11] This is shown in the dynamic analysis of the next section, but a minor example may be given here. In modern aggregative economics rent seems to have disappeared, widening the division between macro- and micro-theory. This is quite unnecessary, for rent (in the sense of periodic contractual payments for the use of real property owned by Households) is simply a payment from Firms to Households,[12] which is constant in the short

[11] The distinction is essential in the analysis of inflation. See my paper "Some Aspects of the Theory of Inflation in a Closed Economy," *Econ. Jour.* (Sept. 1951), LXI, 531-43.

[12] Or from some Households to others. This is not considered here since it merely redistributes income between Households, and such redistribution is assumed to have no effect on total Consumption.

period. Along with interest charges and other overheads, rent enters into the constant α_7 in the Factor Purchase function.

Suppose that the level of rents is revised upwards against Firms. Unless this causes some firms to go out of business α_7 will rise by the same amount and the amount of profits at any given level of National Income will fall correspondingly. It may well be that dividends will fall less (*i.e.*, the fall in b[13] will not entirely offset the rise in α_7) so that there is a net expansionary effect and the equilibrium level of National Income rises.

All this could, of course, be subsumed under the head of a redistribution of income raising the customary consumption function. Since, however, this expansionary effect need not depend on different propensities to consume as between share-owners and real estate owners but can be entirely a matter of redistribution between Firms and Households, it cannot be explained without distinguishing the two sectors.

Another example is given by one aspect of growth economics: in orthodox terms, the problem of explaining why the long-run marginal propensity to consume exceeds the short-run marginal propensity. One possible answer, which has nothing to do with consumer behaviour, is that the marginal propensity to spend of Firms is much less in the short run than in the long run. In the short run, when overheads are fixed, only b of an increase in Sales will be paid out to Households. In the long run, however, if output rises so that Gross Investment exceeds replacement, α_7 will gradually expand, since rents may rise and new capacity will have overhead labour and material costs and may have to bear some interest charges. The ratio of the time rate of increase in α_7 to the rate of investment will depend on such factors as capital intensity, the rate of interest and the debt-equity ratio. In the simple case where all new investment is entirely capital widening, creating new firms with the same capital intensity, dividend policy and debt-equity ratio as existing firms and where the rate of interest is constant over time, the secular rise in α_7 will not be offset by any fall in b. As a result the Factor Purchase function (and hence the orthodox consumption function) will show a secular upward movement, even though the Consumption-Disposable Income function (3) be unchanged.

II. *The Effects of Budget Changes*

The multiplier analysis will now be used to analyse the income effects of changes in the government's budget, both on the revenue and expenditure side.

[13] b may fall not only because of a decrease in the profits-output function but also because of a fall in the dividends-profit function, since the rise in overhead costs may increase the desire of firms to accumulate reserves.

In order to do this it is first necessary to point to an ambiguity in the meaning of a "given budget change." Suppose, for example, that t, the marginal rate of Income Tax net of Transfers, is raised so that at the original equilibrium position the yield of Income Tax minus Transfers is increased by £x. As is evident from Figure 1 and equation (8) this will lower the equilibrium level of both National Income and Factor Purchase. Since the latter determines Income Taxation minus Transfers, it follows that in the new equilibrium their net increase will be less than £x. Furthermore, the other consequential changes will include a fall in the cost of Subsidies and the yield of Indirect Taxation. More generally:

1. Unless a change in government expenditure or taxation has no effect on the variable of which it is a function, the impact change will equal the ultimate change[14] only if the marginal rate of expenditure or tax is zero.

2. Unless all other marginal rates of government expenditure and taxation are zero, the ultimate change in the budget deficit or surplus will equal the ultimate change in the expenditure or tax which is altered only if the alteration has no effect on the variables of which these other expenditures and taxes are functions. Suppose, to give an algebraic example, that the marginal rate of Indirect Tax is raised from k to k',[15] Subsidies being zero. If C_0 is the level of Consumption at market value in the initial equilibrium, the impact increase in the yield of Indirect Taxation will be $(k' - k) \cdot C_0$. Given unchanged values of Investment, Exports and Government Purchases, the resulting fall in National Income will equal:

$$\frac{(k' - k) \cdot C_0 \cdot (1 - j)}{1 - b \cdot (1 - t) \cdot h \cdot (1 - k')}$$

causing a fall in Consumption at market value $b \cdot (1 - t) \cdot h$ times as great, so that the ultimate change in the yield of Indirect Taxation will be:

$$(k' - k) \cdot C_0 \cdot \left(1 - \frac{(1 - j)}{1 - b \cdot (1 - t) \cdot h} \cdot b \cdot (1 - t) \cdot h \cdot k'\right)$$

The fall in the Budget Deficit, or rise in the Budget Surplus, will be less than this by the fall in the yield of Income Tax minus the rise in Transfers,

[14] In the sense of the difference between its value in the initial equilibrium and in the new equilibrium.

[15] The following results can be obtained very simply with the diagram by lowering the lower of the two curves in the N.E. quadrant and finding the new equilibrium position.

$$-\Delta U + \Delta T = -\frac{(k - k')\cdot C_0\cdot (1 - j)\cdot b}{1 - b\cdot (1 - t)\cdot h\cdot (1 - k')}\cdot t$$

The net effect, however, must be to decrease a deficit or increase a surplus; it is impossible for the fall in Income and Consumption to offset the rise in tax rate completely. This can easily be shown. The definitions:

$$\underset{\text{Business Saving}}{S_B} \equiv \underset{\text{National Income}}{Y} - \underset{\text{Factor Purchase}}{F}$$

and

$$\underset{\text{Household Saving}}{S_H} \equiv \underset{\text{Disposable Income}}{D} - \underset{\text{Consumption at market value}}{C}$$

combined with equations (1) and (2) give:

$$\underset{\text{Investment}}{I} + \underset{\text{Exports}}{E} + \underbrace{G+T+L-U-K}_{\text{Budget Deficit}} \equiv \underbrace{S_B+S_H}_{\text{Total Saving}} + \underset{\text{Imports}}{M}$$

By assumption I, E and G are constant, so, taking the differences between the initial equilibrium and the new equilibrium:

$$\Delta T+\Delta L-\Delta U-\Delta K=\Delta S_B+\Delta S_H+\Delta M$$

Since Income falls, so will Saving and Imports, and the left-hand side of this equation must therefore have a negative value too, which means a smaller deficit or bigger surplus.

A generalized analysis of the multiplier effect of budget changes can now be given.

Government expenditures can be classified according to their direct income-creating effect, and an "income-creating coefficient" whose value will be in the range ($0 \rightarrow +1$) can be attached to each type. For example the purchase of newly produced goods with no import content will have a coefficient of unity, while the coefficient for tax-free Transfers will be the marginal propensity to consume of the recipients multiplied by $1 - k$. The coefficient for government purchase of land will be zero or almost zero since this is a sale on capital account.

Similarly, an "income-destroying coefficient" whose value will be in

the range ($-1 \rightarrow 0$) can be attached to each type of government revenue.[16] Thus the coefficient for death duty will be almost zero, and that for indirect tax on goods with no import content will be minus unity if there is money illusion in the consumption function.[17]

With the use of these coefficients the analysis falls into four stages:

1. Calculate the change in each type of expenditure and each type of revenue at the initial equilibrium position.
2. Multiply each such change in expenditure by its (positive) income-creating coefficient and each such change in revenue by its (negative) income-destroying coefficient.
3. Obtain the algebraic sum. This is the multiplicand.
4. Multiply by the multiplier calculated with the new marginal tax and expenditure rates.

It is evident that there are many possible combinations of initial and ultimate change in the deficit or surplus and change in National Income. Consider the set of cases where the budget change is confined to one revenue item and one expenditure item and their impact changes are equal in magnitude and sign so that initially the Budget Deficit or Surplus is unaltered. The multiplicand equals this change multiplied by the algebraic sum of the relevant pair of income-destroying and income-creating coefficients. It obviously may be negative, zero or positive.

In conclusion the special cases where the algebraic sum of the two coefficients is equal to the reciprocal of the multiplier may be noted. Here the change in National Income will equal the change in the budget; the multiplier of a balanced budget change is unity. One of these special cases, illustrated in Figure 2, has received considerable attention of late.[18] Assuming that: (1) Household saving is the only

[16] Compare G. L. S. Shackle, "The Deflative or Inflative Tendency of Government Receipts and Disbursements," *Oxford Econ. Papers*, No. 8 (Nov. 1947), pp. 46-64, where he constructs "inflative and deflative indices," both for full-employment conditions and for under-employment conditions. These are not the same as the coefficients defined above.

[17] As is assumed throughout this chapter; *i.e.*, it is supposed that the function relating Consumption expenditure to money Disposable Income is not shifted when a change in Indirect Tax or Subsidy rates alters the price-level of consumer goods. E. Cary Brown in his paper "Analysis of Consumption Taxes in Terms of the Theory of Income Determination," *Am. Econ. Rev.* (Mar. 1950), XLI, 74-89 shows that even "in the absence of a money illusion, consumption taxes are more effective, dollar for dollar, in cutting back consumer outlays than are income taxes—and this conclusion holds even though everyone be assumed to have an identical marginal propensity to consume. However they are less effective than when a money illusion is present" (p. 85).

[18] See the bibliography given in P. A. Samuelson, "The Simple Mathematics of Income Determination," *Income, Employment and Public Policy* (New York, 1948), p. 140; and Jørgen Gelting, *Finansprocessen i det ØKonomiske Kredsløb* (København, 1948), where four balanced budget multipliers are distinguished.

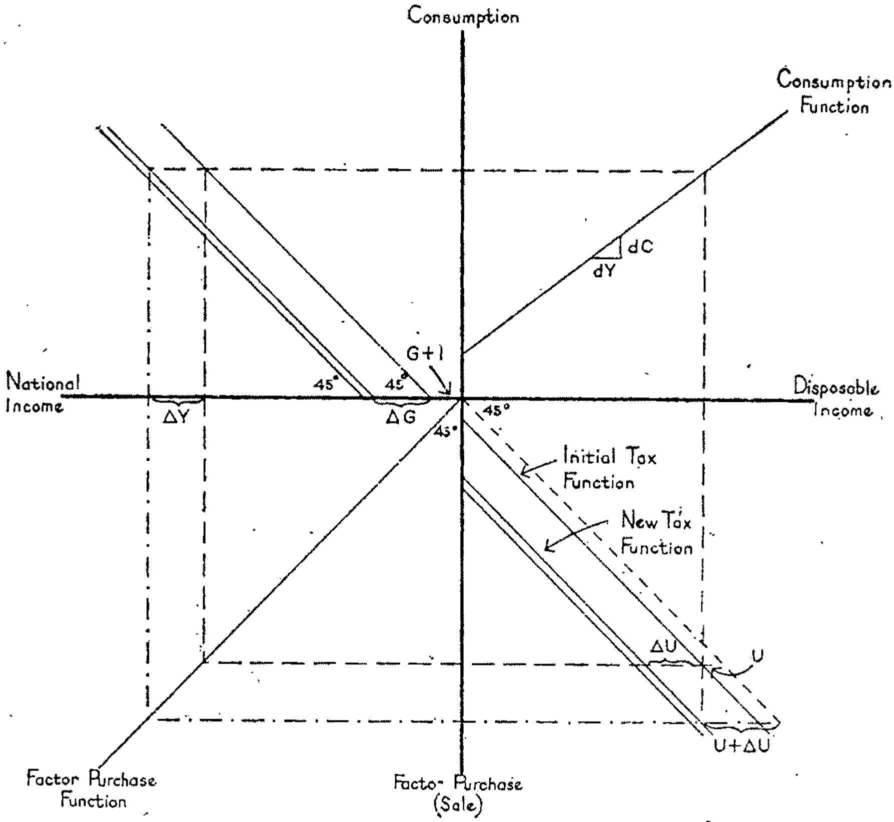

FIGURE 2

leakage; *i.e.,* Business Saving, marginal rates of government expenditure, all marginal tax rates and the marginal propensity to import are all zero so that the ordinary multiplier is the reciprocal of $1 - \frac{dC}{dY}$; (2) Government Purchases (G) and Income Tax (U) go up equally ($\Delta G = \Delta U$); then the impact and the ultimate change in the budget will both equal the change in National Income (ΔY) since the algebraic sum of the two relevant coefficients will be $1 - \frac{dC}{dY}$. This particular special case loses its paradoxical flavour when viewed in the light of a more general analysis.

III. *Some Aspects of the Dynamic Multiplier*[19]

For the purposes of this section, which is concerned with such matters as the multiplier time period and the relation between Saving and Investment during a multiplier process, the most useful method of analysis is that of the Stockholm School with its distinction between prospective (*ex ante*) and retrospective (*ex post*) magnitudes.[20] If the variables of the analysis are to be magnitudes rather than schedules, it is necessary to use what Lindahl calls the "disequilibrium method" where the prices of both goods and factors are fixed and made known at the beginning of each period when purchasers make their plans. The period, which is the interval between the making or revising of plans on the basis of expectations formed in the light of past experience, will be assumed to be coterminous for all Firms and Households.

In order to concentrate on essentials, this section is in terms of a two-sector model without a budget or foreign trade. The equations of the previous section are thus much simplified, the static model becoming:

$$\underset{\text{National Income}}{\mathrm{Y}} = \underset{\text{Investment}}{\mathrm{I}} + \underset{\text{Consumption}}{\mathrm{C}} \tag{1'}$$

$$\underset{\text{Consumption}}{\mathrm{C}} = \underset{\text{constant term}}{\alpha_3} + \underset{\substack{\text{Factor Purchase}\\ (=\text{Factor Sale})}}{\mathrm{h}\cdot\mathrm{F}} \tag{3'}$$

$$\underset{\text{Factor Purchase (Sale)}}{\mathrm{F}} = \underset{\text{constant term}}{\alpha_7} + \mathrm{b}(\underset{\text{Investment}}{\mathrm{I}} + \underset{\text{Consumption}}{\mathrm{C}}) \tag{7'}$$

so that given, as before, the magnitude and composition of Investment,

$$\mathrm{Y} = \frac{\mathrm{I} + \alpha_3 + \mathrm{h}\cdot\alpha_7}{1 - \mathrm{b}\cdot\mathrm{h}}. \tag{8'}$$

For such a closed economy without a budget, the condition of aggregative equilibrium, in the sense that plans shall be fulfilled and expecta-

[19] Parts of this and the first section incorporate, in a revised form, most of the argument of "The Factor and Goods Markets" by Ralph Turvey and Hans Brems, *Economica* (Feb. 1951), XVIII, 57-68. Brems' contribution is to be found in Ch. 4 of his book *Reklame; Købelyst og Købeevne* (Copenhagen, 1950), and he has provided a restatement in his article "Ligevaegt, Forventninger og Planer: Makromodellen," *Nationaløk. Tids.* (1951), LXXXIX, 234-55.

[20] On the methodology of Swedish period analysis see Erik Lindahl, *Studies in the Theory of Money and Capital* (London, 1939), Part I and my chapter "Period Analysis" contributed to W. J. Baumol, *Economic Dynamics: An Introduction* (New York, 1951).

tions realised, is usually stated as the equality of prospective[21] Investment and Saving. The significance and limitations of this condition can only be fully understood by relating it to conditions in the goods market on the one hand and in the factor market on the other hand.[22]

Investment, Business Saving and Household Saving can be defined as follows:[23]

Investment ≡ Purchases of Capital Goods
+Purchases of Intermediate Goods for stock
+Output of all Goods } = market value of increase in Firms' stocks of
−all Sales of Goods } their own products

Business Saving ≡ Output of all Goods } = value added
−Purchases of Intermediate goods for production }
−Purchases of Factors } = all payments by Firms to Households, including dividends

Household Saving ≡ Sales of Factors
−Purchases of Consumption Goods

This gives:

Investment-Saving ≡ all Purchases of Goods
−all Sales of Goods
+Purchases of Factors
−Sales of Factors

Using the terminology of Bent Hansen who was the first to extend and apply this analysis,[24] this can be rewritten:

$$\text{Investment} - \text{Saving} \equiv \text{Goods Gap} + \text{Factor Gap}$$

These identities hold both prospectively and retrospectively. Prospectively a gap is the excess of the value of planned purchases over the value of expected sales. Retrospectively, since every actual purchase corresponds to an actual sale both gaps are of course zero and Investment is identically equal with Saving.

[21] *Prospective* is used to mean *ex ante,* planned, intended or expected; *retrospective to* mean *ex post,* realised or actual.

[22] The following paragraphs on this relationship are based on Grünbaum's "Inkongruente Forventninger og Begrebet Monetaer Ligevaegt," *Nationaløk Tids.* (1945), LXXXIII, 100-18, and part V of Tord Palander, "Om 'Stockholmkolans' Begrepp och Metoder," *Ekon. Tids.* (Mar. 1941), XLIII, 88-141, which will appear in English translation in no. 3 of *Internat. Econ. Papers.* See also E. Schneider, "Saving and Investment in a Closed Economy," *Internat. Econ. Papers* (1951), no. 1, pp. 84-103.

[23] Investment, Saving and Income are taken gross throughout.

[24] See his book *A Study in the Theory of Inflation* (London, 1951), which (*inter alia*) discusses the Factor and Goods markets and the Saving-Investment relation in conditions of suppressed inflation. He uses the word "commodity" where this article used the word "good."

Since equilibrium in the goods market requires a zero Goods Gap and equilibrium in the factor market requires a zero Factor Gap, it is evident that the equality of planned Investment and intended Saving is a necessary, but *not* sufficient condition of aggregative equilibrium in the sense of congruency of plans and expectations.[25]

Suppose, for example, that though prospective Saving and Investment are equal there is a positive Goods Gap and an (equal) negative Factor Gap. If all purchase plans are realised the actual results of the period will be that Firms have sold more than they expected, thus running down stocks, and Households have received a smaller Disposable Income than they expected. As a result, Firms will probably plan to increase their output in the next period and plan a corresponding increase in their Factor Purchase. Households, on the other hand, may lower their Factor Sale (income) expectations and plan a corresponding reduction in their Consumption expenditure. The following period, therefore, will almost certainly not be one of equilibrium; indeed, if the adjustments made by Firms and Households are sufficiently marked, there may be a negative Goods Gap and a positive Factor Gap: a reversal of conditions in the first period. Thus the initial prospective equality of Saving and Investment means very little.[26]

Again, suppose that expected Sales of both goods and factors are above their equilibrium levels and that there is an excess of prospective Saving over Investment. This situation is quite compatible with the existence of a positive Goods Gap if the (negative) Factor Gap is larger. If all purchase plans are realized, the result will be that Firms

[25] For other reasons why prospective equality may not indicate equilibrium see: F. A. Lutz "The Outcome of the Saving-Investment Discussion," American Economic Association, *Reading in Business Cycle Theory* (Philadelphia, 1944), pp. 141-42; Grünbaum, *op. cit.*, sec. 5.

[26] Alvin Hansen in his paper "The Robertsonian and Swedish Systems of Period Analysis," *Rev. Econ. Stat.* (Feb. 1950), XXXII, 24-29, argues that analysis in terms of planned Saving and Investment is inadequate because "income" may mean the income of consumers or the sales by entrepreneurs, but he fails to provide an adequate analysis in terms of the factor and goods markets. Instead, he states on page 28 that "The condition of equilibrium requires *both* that intended investment shall be equal to designed saving *and* that actual investment shall be equal to intended investment. Or what comes to the same thing, the condition of equilibrium requires *both* that intended investment shall be equal to actual investment and *also* that desired (or designed) saving shall be equal to actual saving." This is formally correct, but not very interesting since this condition only indicates, at the *end* of a period, whether there *has been* equilibrium instead of indicating at the *beginning* of a period whether there *will be* equilibrium—*i.e.*, whether plans and expectations are mutually consistent.

The same applies to Harold M. Somers' statement that "The equality of realized and planned saving is sufficient and necessary for an equilibrium of income over time" on page 534 of his "A Theory of Income Determination," *Jour. Pol. Econ.* (Dec. 1950), LVIII. His statement is a definitional relation, since if consumption plans are realised, unintended saving is identical with unexpected income.

sell more Goods than they had expected. Hence they may plan to expand output in the following period, even though a movement towards equilibrium would require a contraction of their output and Factor Purchase.

So far nothing has been said of the capital market;[27] that is, only those money flows have been mentioned whose recipients regard them as being on current account, and the rate of interest has implicitly been assumed to be kept constant by speculation or open-market operations. In order to bring the capital market into the analysis, suppose it to deal in "Securities," these being all things sold on capital account—bills, debentures, shares, real estate, second-hand furniture, etc. Now from Walras' Law, the demand for everything including money is equal to the supply of everything including money, at any arbitrary set of prices, prospectively as well as retrospectively:[28] *i.e.*,

Demand for Goods, Factors, Securities and Money ≡ Supply of Goods, Factors, Securities and Money

so:

Excess Demand for Goods, Factors and Money ≡ Excess Supply of Securities

which can be rewritten as:

Goods Gap + Factor Gap + Net Hoarding[29] − Credit Creation ≡ Excess Supply of Securities (9)

or:

Investment-Saving + Net Hoarding − Credit Creation ≡ Excess Supply of Securities (10)

In contrast to conditions in the factor and goods markets, it may be

[27] As H. G. Johnson complains in his note "The Matrix Multiplier and an Ambiguity in the Keynesian Concept of Saving," *Econ. Jour.* (Mar. 1952), LXII, 197-200.

[28] Compare Bent Hansen's similar presentation of these identities in his paper "Til Renteteorins Almindelige Oplaegning' in *Axel Nielsen: Til Minde* (Copenhagen, 1951). His follow-up is different, however.

J. R. Hicks, *Value and Capital* (Oxford, 1946), Ch. 14, note A, p. 183, says "the difference between planned saving and planned investment is the difference between the planned demand and planned supply for securities in general—including money"; but argues that because of the interdependence of the whole system the "relating of particular equations to particular prices becomes rather idle." This is true for the Hicksian "week"—what Lindahl (*op. cit.*, p. 66) calls the second equilibrium method—but not for the present analysis which uses the disequilibrium method for the factor and goods markets and the first equilibrium method (see *ibid* p. 65) and my chapter "Period Analysis" in Baumol, *op cit.* for the capital market.

[29] Defined as net increase in total money holdings of Firms and Households together.

assumed that in the capital market price is determined during the period by the demand and supply of securities which are thus brought into equality. The identity (10) just derived indicates that this implies that Investment and Saving together with Hoarding and Credit Creation must now be treated as schedules (with respect to the price of securities) instead of magnitudes.[30] Consequently the divergence between prospective and retrospective values of the variables can only be expressed with reference to the price of securities. For example, unintended Investment must now be understood as actual (retrospective) Investment minus the amount of investment planned at the security price determined during the period.

Since the price of securities equates the prospective demand and supply of securities, it can be seen:

1. From (10) that the schedules of Investment, Saving, Hoarding and Credit Creation can be said to determine the price of securities in each period. This is the loanable funds theory of the price of securities.

2. From (9) that, since the sum of the prospective values of: (a) The Goods Gap, (b) The Factor Gap, (c) Net Hoarding minus Credit Creation, is made zero through the working of the capital market, the condition of aggregative equilibrium can be stated as the requirement that any two of them shall be zero. It follows that neutral money (equality of prospective Net Hoarding and prospective Credit Creation) is not a sufficient condition for equilibrium.

3. From (9) that, if all purchase plans are realized and if actual Credit Creation equals its planned value,[31] the unintended Net Hoarding of Firms will equal their unexpected Sales (the Goods Gap) and the unintended Net Hoarding of Households will equal their unexpected income (the Factor Gap).

It has been assumed above that payment and purchase coincide—that there is no trade credit. If this assumption is relaxed, retrospective purchases of securities will exceed prospective purchases to the extent that Firms sell more goods and hence give more trade credit than they had expected. Allowance for this introduces considerable complications.

For the remainder of this paper the problems of the capital market will be ignored through the assumption that the price of securities is kept constant by open-market operations, so that Factor Purchase, Investment, etc., can be spoken of as magnitudes.

The objection raised here to analysis in terms of Saving and Investment is, of course, only an aspect of the aggregation problem. Just as a prospective equality of Saving and Investment may conceal a positive

[30] Unless their interest elasticity is zero.

[31] This will be the case if Credit Creation takes the form of the purchase of Securities

Goods Gap and an equal negative Factor Gap, so may a zero Goods Gap conceal a negative Trombone Gap and an equal positive Ear Plug Gap. The point of the division between the factor and goods markets is that this is the most useful of the possible single divisions, at least for short-run analysis. In particular, this division is essential in order to make clear the relationship between prospective and retrospective Saving and Investment during a multiplier process. In order to demonstrate this the following assumptions will be made:

1. All purchase plans are realised, so that divergence between prospective and retrospective magnitudes is entirely a matter of unexpected Sales.

2. The planned Consumption of any period is a function of the Factor Sale expected; similarly the planned Factor Purchase of any period is a function of the sum of the expected Sales of consumer goods and planned Investment.

3. The Sales, of goods or factors, expected for any period equal the actual Sales of the preceding period.

Assumptions (2) and (3) mean that aggregative equilibrium implies constancy of National Income and its components and they make the Swedish treatment in terms of expectations and plans equivalent to models which have a simple one-period lag in the behaviour equations.[32]

The dashed lines in Figure 3 show an initial equilibrium assumed to exist in Period 0. Investment is I, Consumption OV, National Income (their sum) is OZ and Factor Purchase (equals Factor Sale) is OX.

Now suppose that beginning in Period 1 some Firms increase their rate of purchase of capital goods so that planned Investment rises from I to I′ and remains at that level in subsequent periods. This means that the curve in the N.W. quadrant, which adds planned Investment to expected Sales of consumer goods, shifts leftwards by I′ − I. Since, by assumption (3) the increased purchases of capital goods is not anticipated, the increase in planned Investment creates a Goods Gap of SZ. Since planned Factor Purchase and expected Factor Sale are still both OX, this Goods Gap is equal to the excess of planned Investment over intended Saving. Retrospectively, the Goods Gap will be closed and Investment made equal to Saving by unintended disinvestment (unexpected Sales) of SZ on the part of the Firms selling capital goods.

In period 2 the Sales expectations of Firms will be increased by SZ. Since planned Investment[33] is assumed to remain at I′ and Consumption has not yet increased, the Goods Gap is zero. Planned production will

[32] Similarly, the assumption of correct expectations is equivalent to an unlagged behaviour equation.

[33] Stock replacement is thus neglected. L. A. Metzler, "The Nature and Stability of Inventory Cycles" (*Rev. Econ. Stat.* [Feb. 1941] XXIII, 13-29), includes it in part of his

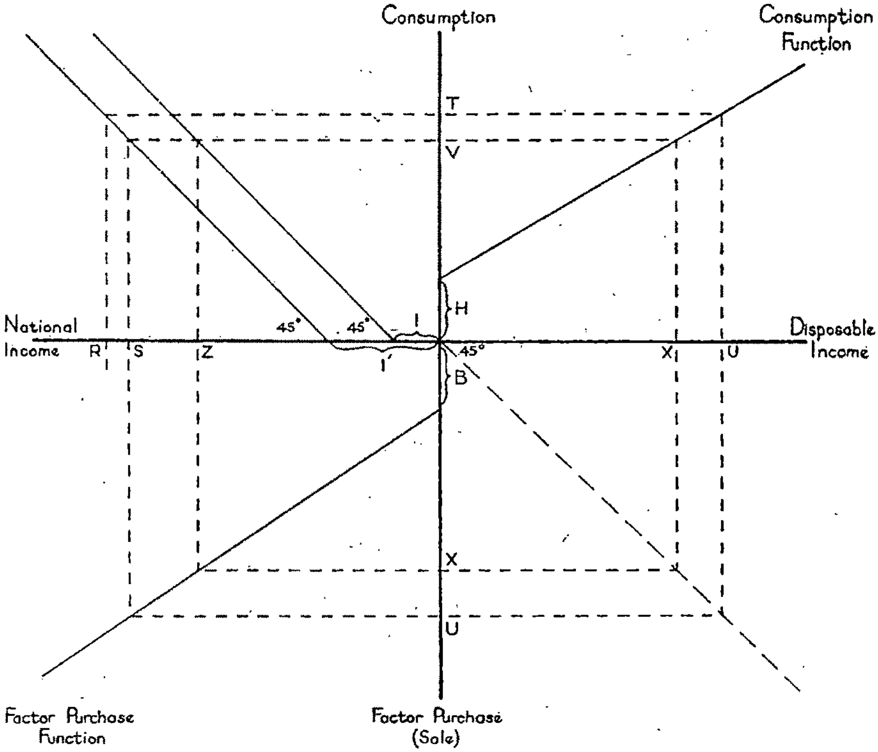

FIGURE 3

rise equally with expected Sales (by SZ) and planned Factor Purchase by b times this amount, that is by XU. Expected Factor Sales, however, are only OX (equal to actual Factor Sales in Period 1) so there is a Factor Gap of XU equal to the prospective excess of Investment over Saving. Retrospectively, the Factor Gap is closed and Saving raised to equal Investment by unexpected Factor Sales (Disposable Income) of XU, constituting unintended Saving.

Similarly in Period 3, the excess of Investment over Saving will be a matter of a Goods Gap of RS. Thus Period 3 is qualitatively the same as Period 1. This means that the income-generation period is two periods in length. What is the relationship between this and the customary statement[34] that the income-generation period is the sum of three lags: Income → Spending; Spending → Production; and Production → Income?

The answer is given by assumptions (2) and (3) above. As applied to Households they make the Income → Spending lag equal to the plan-revision period of Households, and as applied to Firms they make

[34] See Metzler's valuable paper "Three Lags in the Circular Flow of Income," *Income,*

the Spending → Production lag equal to the plan-revision period of firms.[35] The Production → Income lag has been ignored by the assumption that the Factor Purchase corresponding to the production of any period is made during that same period.

In either of two special cases, analysis of the multiplier process in terms of Saving and Investment is adequate:

1. Firms anticipate their Sales correctly so that the Goods Gap is always zero and the Factor Gap equals the prospective excess of Investment over Saving. Their retrospective equality is thus brought about entirely by unintended Household Saving.[36] This case may be called the Robertsonian multiplier, since the concept of Consumption depending on today's disposable income, which is the income earned yesterday, is equivalent to a one-period lag in the consumption function,[37] and Robertson does not distinguish planned and realised Investment.

2. Households anticipate their income (Factor Sales) correctly so that the Factor Gap is always zero and the Goods Gap equals the prospective excess of Investment over Saving. Their retrospective equality is thus brought about entirely by unintended Investment. This case may be called the Lundbergian multiplier.[38]

This treatment of the income-generation period as the sum of three simple lags is, of course, very abstract, even apart from the assumption that the plan-revision periods of all Firms and Households are of the same length and coincident. In particular, the Spending → Production lag can be treated as a simple lag only if all industry is fully integrated vertically.[39] While such complications destroy the simplicity of the two-sector model they do not, however, affect many of the conclusions reached with its aid. Thus a model with twenty goods markets would

[35] It is assumed here that the plan-revision periods of Firms and Households are of the same length.

[36] On the definitions used above there can be no unintended Business Saving if, as is assumed, all output and purchase plans are realised. A different assumption is made by Bent Hansen in his *A Study in the Theory of Inflation* (London, 1951), pp. 32-35.

[37] See Metzler's article on the three lags, *op. cit.*, pp. 17-18.

[38] Erik Lundberg, *Studies in the Theory of Economic Expansion* (London, 1937), Ch. 9, and Metzler's article on inventory cycles, *op. cit.* Both of these, however, bring in stock replacement in a later part of their analysis which is not the case in the present analysis, planned Investment being assumed constant. R. Eisner "The Invariant Multiplier," *Rev. Econ. Stud.* (1949-50), XVII (3), 198-202, points out that in this case National Income is always equal to actual Investment times the multiplier.

[39] Removal of this assumption requires a many-sector model. The necessary mathematics have been provided by Richard M. Goodwin, *op. cit.*, Richard Stone "Simple Transaction Models, Information and Computing," *Rev. Econ. Stud.* (1951-52), XIX (2), 67-84 and John S. Chipman, *op. cit.* The latter introduces an ingenious way of allowing for lags of different length.

The economics of the Spending → Production lag are excellently discussed by Gardner Ackley in section 2 of his article "The Multiplier Time Period," *Am. Econ. Rev.* (June 1951), XLI, 350-68.

have twenty Goods Gaps and twenty kinds of possible unintended Investment, but it would still be true that the latter arises from mutual inconsistency of plans and expectations concerning the production, sale and purchase of goods.

In conclusion, it is worth examining the belief that the income-generation period is equal to the reciprocal of the velocity of circulation of active money.[40] This belief is not true, whether the lags composing the income-generation period be simple lags or weighted averages, for the following reasons:

1. The plan-revision period of Firms and Households need not equal the length of time for which they hold active money balances. For example if a Household receives its income at the beginning of a period and disburses it evenly through the period, it holds money on the average for only half a period.

2. Money received on current account and used to finance Imports or security purchase will later be used to finance Exports or Investment. The speed of this will affect income-velocity but not the income-generation period.

3. Increased dealings in the capital market on capital account will increase active balances (or raise their speed of turnover) without affecting the income-generation period.[41]

4. If there is trade credit so that payment follows purchase "the speed of the flow of the new money is seen to depend on the rate at which an added flow of new goods is forthcoming, and there exists no logical reason for supposing that the rate at which production increases will bear any connection with any pre-existing speed of money flows."[42] Thus the marginal income-generation period may be very different from the average and any calculable income velocity is relevant, if at all, only to the latter.

[40] Fritz Machlup maintained this in his paper "Period Analysis and Multiplier Theory," American Economic Association, *Readings in Business Cycle Theory* (Philadelphia, 1944) where he defined this reciprocal as "the period in which total incomes are equal to the total of active balances" this being "the time which it takes the money in active circulation to complete a circuit flow from income recipient to income recipient" (p. 208). This is "Income Period E." He made a number of reservations, however, some of which are elaborated below.

Some of the following points were made earlier in my article "The Multiplier," *Economica* (Nov. 1948), XV, 267.

[41] Some authors beg these last two points by explicitly ignoring "the financial circulation" which they fail to define adequately.

Machlup states that "An increase in transactions arising from the transfer of assets might lengthen the income period; an increase in the use of money substitutes and of clearing arrangements might shorten the income period. The effects on the propagation speed of the new income flow may be considerable (*op. cit.*, p. 215). This simply assumes equality of the two periods.

COMPARABILITY OF LABOR CAPACITIES OF FARM AND NONFARM LABOR*

By D. GALE JOHNSON

> When watching the action of demand and supply with regard to a material commodity, we are constantly met by the difficulty that two things which are being sold under the same name in the same market are really not of the same quality and not of the same value to the purchasers. Or, if the things are really alike, they may be sold even in the face of the keenest competition at prices which are nominally different, because the conditions of sale are not the same. . . . But difficulties of this kind are much greater in the case of labour than of material commodities: the true price that is paid for labour often differs widely, and in ways that are not easily traced, from that which is nominally paid.[1]

In the above paragraph and his later discussion, Marshall indicates that wage rates or money earnings, by themselves, provide an inadequate picture of the functioning of the labor market because the laborers being compared are not of equal efficiency or the conditions of sale of labor are dissimilar. Any analysis of the functioning of the farm labor market is beset by difficulties of both kinds. This is especially true if one wishes to determine whether the labor market has tended to equalize the returns to farm and nonfarm labor. In this paper only the first of the two main problems is considered—the general question of the efficiency of the farm work force compared to the nonfarm work force.

Because the word "efficiency" has so many different connotations, the term "labor capacity" is used in its place. Our measure of the labor capacity of the farm labor force is the job distribution that a random sample of the farm labor force would have in nonfarm employment if each worker held the job which for him had the greatest net advantage. This measure is subject to two restrictions: it relates to a given time

* The research on which this article is based has been done on a project financed by a grant for Agricultural Economics Research at the University of Chicago by the Rockefeller Foundation. Financial assistance was also received from the National Security Resources Board. The author, professor of economics at the University of Chicago, is indebted to Jack Ciaccio and Marjorie Penniman for assistance in making the detailed statistical tabulations, and to T. W. Schultz and O. H. Brownlee for certain critical observations.

[1] Alfred Marshall, *Principles of Economics* (London, 1936) 8th ed., pp. 546-47.

and it assumes that farm migrants find jobs in competition with the nonfarm labor force, as it actually exists at the time, in a given labor market. The measure of relative labor capacity that can be determined is ratio of the average money earnings reflected by the (hypothetical) nonfarm job distribution of farm labor force to the average money earnings of the nonfarm work force. The measure assumes that farm people have the same set of attitudes concerning the nonmonetary advantages and disadvantages of nonfarm jobs as do nonfarm people.[2]

This study attempts to determine the relative labor capacity of farm people by analysis of the job experience of farm persons who have migrated to nonfarm areas. The materials have come largely from the 1940 Census of Population and cover persons who migrated from farms between January 1, 1935 and the time the 1940 Census was taken.[3] The general approach has been to estimate the money earnings reflected by the farm-nonfarm migrant population, standardized to eliminate the effects of age, sex and color differences relative to the parent farm population, and to compare this estimate to the labor earnings of the nonfarm population. The conclusions reached later are based upon two significant hypotheses: (1) The migrants from farm areas are representative of the parent population in all significant characteristics, excepting age, sex and color. (2) The actual job experience of farm migrants in nonfarm areas is indicative of the labor capacity of farm migrants. This implies that recent migrants from farms are able to find the jobs for which they are best suited under given labor market conditions.

It has not been possible to find evidence that would support or reject the second hypothesis. It seems probable that the first job held by many migrants is not the one best suited to his particular labor capacities. The average time the farm migrants had been in nonfarm communities was approximately two and one-half years. Consequently, the majority of them had had an opportunity to search for different jobs, though an important fraction had not. It is quite possible therefore that the dependence of the analysis upon this hypothesis has had the effect of a slight underestimation of the labor capacity of farm people.

[2] Reference is made only to the labor capacity of farm people as evidenced by the nonfarm jobs they might hold and not also to the farm jobs nonfarm people might hold. This has been done because the net transfer of labor in the United States has been from farm to nonfarm and the relevant comparison is the one chosen.

[3] A migrant was defined as a person who lived in 1935 in a county or city of 100,000 or over, different from the one in which he lived at the time the 1940 Census was taken. Thus not all persons who changed from a farm to a nonfarm residence between 1935 and 1940 were counted as migrants if the move was within a county and not to a city larger than 100,000.

I. *Selectivity of Rural Migration*

Migration from farm to nonfarm communities is a selective process with respect to certain population characteristics. The migrants included in the present study were younger than the parent population.[4] The migrant stream included slightly fewer males[5] and significantly fewer nonwhites than the rural farm population of 1940.[6]

Selectivity of migration with respect to age, sex and color is of little significance in the present instance. The effects of these types of selectivity can be reflected in our estimates of labor capacity. Migration, however, may be selective with respect to other characteristics that are related to labor capacity, such as intelligence, manual dexterity and education. The hypothesis that the farm migrants to nonfarm areas represent a random sample of the parent farm population with respect to characteristics other than age, sex and color is not rejected by three different types of evidence that bear on the issue.

1. The median number of years of school completed by farm migrants 25 to 34 years old was almost identical to that of the farm population of the same age—about 8 years of schooling. About 11.5 per cent of the migrants had some college education compared to 8.8 of the rural farm population. Almost the same proportion graduated from college (4.3 and 3.8 per cent). It does not appear that the farm migrants were appreciably better educated than the farm nonmigrants.[7]

2. If there is a positive relation between the labor capacity of farm migrants and the level of farm income in their original community, the distribution of farm migrants by the region of origin does not indicate that the farm migrants came predominantly from either the high or low farm income regions. An analysis of the data on net off-farm migration rates by states for the decade of the 'thirties as a whole revealed a weighted correlation of −0.38 between the level of net farm income per worker and the rate of migration from farms. The correlation coefficient, which is just significant at the one per cent level, indicates that the low income states had a somewhat higher rate of net off-farm

[4] The white farm migrants to nonfarm areas had a median age about 10 years lower than the white farm nonmigrants if only persons over 14 are included. The nonwhite median for migrants was about 4 years lower than for the nonwhite farm nonmigrants. See Sixteenth Census of the U.S., 1940, *Population, Internal Migration, 1935 to 1940, Age of Migrants,* Table 9.

[5] See Sixteenth Census, *Population, Internal Migration, Social Characteristics of Migrants,* Table 2.

[6] See Sixteenth Census, *Population, Internal Migration, Color and Sex of Migrants,* Table 2. The nonwhite farm population was 16.2 per cent of the total farm population in 1940; only 12.2 per cent of the farm migrants to nonfarm communities were nonwhites.

[7] Sixteenth Census, *Population, Internal Migration, Social Characteristics of Migrants,* Table 7.

migration than the higher income states. However, it should be noted that for the particular group of migrants included in our data, the regional distribution of the origin of migrants did not indicate any relationship between the level of farm incomes and the rate of migration.

3. There have been several score of studies made for individual communities in an attempt to determine if migrants represent a selected group from the parent population that is in some way superior or inferior. These studies, made by sociologists, have used various definitions of superiority or inferiority, but most of the research workers had in mind a concept that had a significant relation to economic productivity. In a review and analysis of this literature, Dorothy S. Thomas found four conflicting hypotheses: (1) Cityward migration selected the superior elements of the parent population; (2) Cityward migration selects the inferior elements; (3) Cityward migration selects from the extremes; and (4) Cityward migration represents a random sample of the parent population. She concludes as follows: "We have, then, evidence of a sort that migration selects the better elements, the worse elements, both the better and the worse, and also that it is unselective. Even though we may decide that the evidence cited is tenuous, it is not improbable that selection does operate positively, negatively, and randomly, at different times, depending on a variety of factors that, up to the present, have not been adequately investigated."[8]

Sorokin and Zimmerman arrived at the following conclusions from an analysis of the literature: "There is no valid evidence that migration to the cities is selective in the sense that the cities attract in a much greater proportion those from the country who are better physically, vitally, mentally, morally, or socially, and leave in the country those who are poorer in all these respects [italics omitted]. There is also no evidence that the reverse is true."[9]

Though I have not been able to provide evidence denying the possibility of selectivity in the migration process, it is significant that the hypothesis that no important degree of selectivity exists cannot be rejected on the basis of available data. Consequently, in this paper it is assumed that there is no selectivity.

II. *Occupational Experience of Rural Farm Migrants to Nonfarm Areas*

The published data from the 1940 Census of Population do not provide estimates of the wage and salary incomes of farm migrants to nonfarm areas. The published data indicate the employment status of the

[8] Dorothy S. Thomas, "Selective Migration," *The Milbank Memorial Fund Quart.*, 1938, XVI, 403-07.

[9] Sorokin, P. and Zimmerman, C. C., *Principles of Rural-Urban Sociology* (New York, Henry Holt and Co., 1929), p. 582.

migrants and the occupational category of the employed migrants. On the basis of certain assumptions, which are indicated below, these data are translated into an estimate of annual labor earnings of the migrant group.

Recently the Bureau of the Census tabulated data on the wage and salary incomes of farm migrants to urban areas for samples of migrants from the Corn Belt and from the Cotton Belt. The wage and salary incomes relate to 1939; consequently, some of the migrants were still living and working in farm areas during part or all of 1939. Thus the wage and salary data cannot be used directly but required adjustment to reflect the effect of lower money incomes on farms as well as for the more obvious adjustments for age. In this section, I will present the results obtained from the published data and later show the degree of consistency between the two sets of estimates.

A. *Incidence of Unemployment*

These data, summarized in Table I, indicate that rural farm migrants to urban areas had almost identically the same employment status as the urban population. Of those classified as members of the labor force, 84.4 per cent of the farm migrants were employed while 84.7 per cent of the labor force members resident in urban areas were employed.[10] Some difference does exist in the case of migrants to rural nonfarm areas. Roughly 3 per cent fewer migrants than nonmigrants were employed.[11]

Corroborating data are provided by a Census sample survey of the employment experience of migrants in 1948. These data cover migrations of one-year duration or less. In this case migrants had rather different rates of unemployment than the nonmigrants. However, the male migrants from farm to nonfarm areas had roughly the same proportion of unemployment (9.2 per cent) as the migrants from nonfarm to nonfarm areas (8.1 per cent).[12] These rates of unemployment were much higher than for the total male population, which was 3.6 per cent. The higher rate of unemployment among the migrants was probably due to the relatively short time interval considered.

[10] No difference remains when the employment data are adjusted for the differences in age distribution.

[11] Farm migrants to farm areas had the same employment status as the total farm population.

[12] Bureau of the Census, *Current Population Reports, Labor Force*, Series P-50, No. 10, Table 4. The two figures could have been drawn from the same populations. (See *ibid.*, p. 5.)

TABLE I.—DISTRIBUTION OF RURAL FARM MIGRANTS AND TOTAL POPULATION IN THE LABOR FORCE IN URBAN AND RURAL NONFARM AREAS BY EMPLOYMENT STATUS, 1940, FOR U.S.*
(Per cent)

B. *Occupational Distribution of Employed Migrants*

The previous section indicated that farm migrants to nonfarm areas found employment as readily as nonmigrants, if a certain time for adjustment was allowed. The question to which we now turn is the nature of the jobs which the farm migrants obtained.

Table II compares the occupational distribution for employed male and female migrants to urban and rural nonfarm areas with the occupational distribution of the nonmigrants. In the table, the occupational groups are ranked according to the medium wage or salary income of male workers employed for 12 months in 1939.[18]

It will be noted that the farm migrants to urban areas are not as fully represented in the higher income groups as the urban nonmigrants are. In the top four groups, which contain 56.4 per cent of the nonmigrants, are found only 38.0 per cent of the farm migrants and much the same situation prevails in the rural nonfarm areas—45.0 per cent of the nonmigrants fall in the top four groups while only 28.1 per cent of the farm migrants do. Comparison of female farm migrants and nonmigrants shows much the same thing.

The importance of the differences in the occupational distribution of the migrants and nonmigrants depends upon the differences in the wages in the various occupational groups. If the wage differences were substantial, one would expect the occupational distribution of the farm

[18] There are only minor differences between the ranks of wages and salaries for males and females. (See Table III.)

TABLE II.—PERCENTAGE DISTRIBUTION AMONG MAJOR OCCUPATION GROUPS OF EMPLOYED FARM MIGRANTS AND NONMIGRANTS, BY SEX, IN URBAN AND RURAL NONFARM AREAS IN 1940

	Male		Female	
	Non-migrants (per cent)	Farm Migrants (per cent)	Non-migrants (per cent)	Farm Migrants (per cent)
Urban				
Proprietors, Managers and Officials	12.4	5.4	3.7	1.4
Professional and Semiprofessional	6.5	3.9	11.2	13.7
Clerical and Sales	18.4	12.7	33.5	16.8

migrants to reflect substantially lower income than the occupational distribution of nonmigrants. One way of determining the extent of the difference is to weight the occupational distribution by the median incomes actually received in each occupation. The census provides information on the money income from the receipt of wages and salaries. Any nonmoney income such as the perquisites to farm laborers and domestic servants is not given. The income of self-employed persons is also excluded. Likewise data are available only for the United States as a whole and not for urban and rural nonfarm areas. Of the three main limitations of the data, only the first—failure to include nonmoney wage or salary income—is important. Since relatively few urban work-

TABLE III.—INCOME REFLECTED BY OCCUPATIONAL DISTRIBUTION OF EMPLOYED FARM MIGRANTS AND NONMIGRANTS IN URBAN AND RURAL NONFARM AREAS, BY SEX, 1939

Residence in 1940 and Sex	Farm Migrants (dollars per year)	Nonmigrants (dollars per year)	Per Cent Migrants of Nonmigrants
Urban			
Male	1075	1260	85
Female	560	700	83
Rural Nonfarm			
Male	960	1160	83
Female	590	660	89

Based on data in Table II and data below.
Median annual wage and salary incomes by occupational groups were as follows:

	Male	*Female*
Proprietors, Managers, and Officials	$2,136	$1,107
Professional and Semiprofessional	1,809	1,023
Clerical and Sales	1,359	883
Craftsmen and Foremen	1,309	827
Operatives	1,007	582
Service, except Domestic	833	491
Laborers, except Farm	673	538
Domestic Service	429	296
Farmers and Farm Managers	373	348
Farm Laborers	309	76

* Source: Sixteenth Census, *Population*, Vol. III, *Labor Force*, Part I, Table 72. In calculating medians, incomes of less than $100 were not included to exclude most unpaid family workers. Comparisons do not entirely eliminate effects of age.

ers fall in the self-employed category, failure to include income from that source is unimportant.[14]

The results of these calculations are presented in Table III. They show that the income reflected by the occupational distribution of the rural farm migrants, had they received the median income of each occupational group, would have been somewhat less than the income reflected by the occupational distribution of urban and rural nonfarm nonmigrants. The differences are of the magnitude of 11 to 17 per cent less.

Are these differences due solely to the different innate capacities of the groups being compared? One obvious source of difference is age.

[14] Out of a total of 40,450,000 male workers in 1948, something less than 4,000,000 were self-employed in pursuits other than agriculture. The earnings of the self-employed professional workers in 1947 who were about one-third as numerous as the salaried professional workers, were about 40 per cent greater than the income of salaried professionals. However, most of the self-employed were in the proprietors, managers, and officials group and the self-employed earned about a sixth less than the salaried. See Bureau of the Census, *Current Population Reports*, Series P-60, No. 5, Table 17.

The farm migrants are younger than the nonmigrants in the areas to which the farm migrant went. Farm migrants to nonfarm areas fall into age brackets that earn less than the average of either the parent or the absorbing population.

The calculations given in Table III eliminate the effect of age upon the level of earnings within an occupational group. An adjustment of the data to include the effects of age upon the occupational distribution of a population can be made by comparing the occupational distribution of nonfarm people of the same age distribution as the farm migrants with the actual occupational distribution of nonfarm people.

Such an analysis cannot be made directly from the data at hand. Census data are available showing the occupational distribution by age only for the country as a whole and not for nonfarm groups. This distribution was adjusted by omitting farmers and farm managers and farm laborers. The Census data gave the age distribution of farm persons migrating to urban areas, but not all such migrants were in the labor force. It was assumed, since the proportion of the migrants that was in the labor force was roughly the same as for urban nonmigrants, that for any age group labor force participation was the same for rural farm migrants and urban nonmigrants.

When these adjustments were made, it indicated that the income reflected by the actual age distribution of the male farm migrants was $1,230 while the male urban nonmigrants, excluding farmers and farm laborers, had an average of $1,270.[15] This would indicate a difference of roughly $40 due to occupational differences associated with the age distribution of farm migrants. If this adjustment is applied to the data in Table III, it would mean that the male farm migrants to urban areas would earn on the average about 11 per cent less than male urban nonmigrants. This would be an income level roughly equal to the average incomes of (1) operatives and (2) craftsmen and foremen.

All of the above calculations on wage earnings relate, of course, to the given set of relative wage incomes by occupational groups. A different set of relative wages combined with either the same or different occupational distribution of migrants and nonmigrants would result in a different comparison of labor earning possibilities.

Data on wage or salary incomes by occupational groups comparable to the data used in the previous analysis are available for 1950.[16] A comparison of the changes in wage or salary incomes by occupational groups indicates that the groups in which farm migrants are concen-

[15] See Sixteenth Census, *Population*, Vol. III, *Labor Force*, Part 1, Table 65, for occupational distribution by age.

[16] See Bureau of the Census, *Current Population Reports, Consumer Incomes*, Series P-60, No. 9, Table 25.

trated to a greater degree than the urban population had the greatest relative rise in earnings. This change in relative wage rates had the effect of reducing the differential between the earnings value (before adjustment for the effect of age on occupational distribution) of male urban nonmigrant and the farm migrants occupational distribution from 15 per cent to 10 per cent. After adjustment for the effects of age, the earnings of male farm migrants were about 8 per cent less than the male urban nonmigrant.[17]

The conclusion that one might draw from this analysis is that labor employed in agriculture, on the average, has a labor income capacity of roughly 90 per cent of the labor income capacity of our urban and rural nonfarm populations, for similar age and sex distributions.

This estimate is for the nation as a whole. The migrants from different regions may have fared rather differently. The next section analyzes the experience of migrants by region of origin.

TABLE IV.—INCOME REFLECTED BY OCCUPATIONAL DISTRIBUTION OF FARM MIGRANTS TO URBAN AND RURAL NONFARM AREAS CLASSIFIED BY REGION OF ORIGIN AND SEX, 1939*

Residence in 1940 and Sex	Region of Origin			
	Northeast	North Central	South	West
Urban				
Male	1125	1120	1030	1280
Female	620	590	555	650
Rural Nonfarm				
Male	960	1035	910	980
Female	575	640	545	670

* Source and method of calculation: see Table III. The income reflected by the occupational distribution of nonmigrants for urban areas was $1,260 for males and $700 for females and for rural nonfarm areas was $1,160 for males and $660 for females.

III. *Occupational Experience of Farm Migrants from Different Regions*

The farm migrants from different regions to nonfarm areas did not achieve the same occupational distributions. Table IV shows the earning value of the occupational distributions of the migrants from the four regions to urban and rural nonfarm areas. The West farm migrants to urban areas had the highest earning value, while the South farm migrants had the lowest when the migrants went to urban areas. The North Central farm migrants did the best of migrants to rural nonfarm areas while the South farm migrants did the least well.

[17] Calculations for migrants to rural nonfarm areas indicate a difference of 10 per cent at the 1950 relative wage levels.

The relatively poor showing of the South seems to be due to the color composition of the South migrants. The published Census data did not give separate data for the occupational distribution of whites and nonwhites. However, a special tabulation of data from the 1940 Census of Population permits a comparison of the occupational distribution of male white farm migrants to urban areas for the Cotton Belt and the Corn Belt.[18] A calculation of the income value reflected by the occupational distributions was the same as for the Corn Belt.[19]

Consequently, if the occupational distributions accurately reflect the capacity of the farm migrants and thus of the farm population, it may be concluded that the labor capacity of the white farm labor force in the South is approximately the same as in the rest of the nation. This conclusion is somewhat surprising in light of the significant differences that exist between agricultural labor earnings in the South and in the rest of the nation.[20] The writer considered the possibility that the farm migrants in the South came in disproportionate numbers from the rural areas with the highest farm incomes. This might then explain the relative ease with which Southern farm people fit into the nonfarm occupation pattern.

The hypothesis does not appear to be valid, however. Though data are not available to show the origin of white farm migrants by small

[18] For a description of the sample, see Section IV below.

[19] Though the Cotton Belt does not include all of the South and the Corn Belt does not include all of the North Central States, the income value reflected by the farm migrants in the Cotton Belt farm (both white and nonwhite) migrants differed from that of the South as a whole by less than one per cent, while the difference between the Corn Belt and the North Central States was about three per cent. This indicates that the samples were quite representative of the larger areas. These calculations and those referred to in the text assume that the rates of pay in the same occupational groups were identical in all regions. The validity and significance of this assumption is discussed in Section IV.

[20] For the years 1940 and 1945, the writer has estimated that annual labor returns to farm workers were as follows (in dollars):

Region	*1940*	*1945*
United States	$385	$1,135
New England	505	1,090
Middle Atlantic	565	1,105
E. N. Central	505	1,455
W. N. Central	500	1,745
S. Atlantic	260	710
E. S. Central	260	540
W. S. Central	315	760
Mountain	505	1,560
Pacific	530	2,202

These data relate to all labor in the South. Adjustments based on the relationship between the value of products sold, traded or used on farms of white farm operators and all farm operators in the South, result in estimates of labor income for white farm labor 10 to 12 per cent higher than those given above. Since some Negro labor is used on farms operated by white operators, there is a small, but undertermined, downward bias in the estimates of white farm labor income in the South.

areas, such as counties, data on all farm migrants indicate that the rate of migration is as high, if not higher, from counties with the lowest levels of living as it is from counties with the highest levels of living.[21]

IV. *Wage or Salary Income of Farm Migrants to Urban Areas*

Because wage and salary data were not available for all farm to urban migrants, it was necessary to derive an estimated level of earnings from their occupational distribution. This estimate was based on the assumption that the median earnings of the migrant were the same as the median earnings for the occupational group involved. Through the cooperation of the Bureau of the Census, it has been possible to obtain the wage and salary data for 9,500 migrants from the Corn Belt, 8,900 white and 4,000 nonwhite migrants from the Cotton Belt to urban areas.[22]

The wage or salary data for the sample of migrants cannot be directly compared with the data provided in the Census for any urban group. First, the wage or salary income is for the year 1939 and at least 24 per cent of the individuals included in the sample resided on farms part or all of 1939. Thus, the income data do not indicate directly the income of the farm migrants in urban occupations. Most of the individuals who lived on farms some part of 1939 either would not have had any wage or salary income while living on farms because they were farm operators or unpaid family workers or would have worked as farm laborers at a lower level of money income than the average urban wage or salary level. Second, the age distribution of migrants is substantially different from that of urban nonmigrants. Despite these two difficulties, the availability of these data provide an opportunity to check the general validity of the assumptions involved in the earlier analysis.

The migration period covered in the Census questionnaire was from April 1, 1935 to the time the Census enumeration was actually made,

[21] The countries in the 16 states of the South were divided into quartiles according to the rural farm level of living index developed by Hagood. The average (unweighted) migration rates for the counties in each quartile were calculated for 1930-40 decade. The quartiles had the following average rural level of living indexes: 1st, 108; 2nd, 85; 3rd, 74; and 4th, 60.6. The average migration rates were: 1st, minus 13.1; 2nd, minus 13.1; 3rd, minus 15.4; and 4th, minus 13.2. Source of data: as to levels of living: Margaret Jarman Hagood, "Rural Level of Living Indexes for Counties of the United States, 1940" (Washington, 1943); and as to migration: Eleanor H. Bernert, "County Variation in Net Migration from the Rural Farm Population, 1930-40" (Washington, 1944).

[22] These data were obtained jointly by the Scripps Foundation for Research in Population Problems of Miami University, the Bureau of Agricultural Economics of the United States Department of Agriculture, and Agricultural Economics Research of the University of Chicago. Mr. and Mrs. Donald J. Bogue contributed substantial amounts of their time and energy to the study. It should be noted that the sample included only migrants that remained within the same state.

which was subsequent to April 1, 1940. Thus persons who migrated within an approximate 15-month period following January 1, 1939 would have spent some time on farms during 1939. On the basis of Bureau of Agricultural Economics estimates of departures from farm to nonfarm areas, and assuming that there was no greater memory bias for migrants leaving farms from 1935 through 1938 compared to migrants after that date, 24 per cent of the migrants lived part or all of the year 1939 on farms. The wage or salary income of male farm residents in 1939 was substantially below that of urban residents. In fact, for employed male farm residents without other income, but with $1 or more of income, it was $369; for the employed male urban resident, the median was $1,188.[23] Further, 30.5 per cent of the employed male farm residents without other income had no money income and presumably were unpaid family workers, while only 5.6 per cent of the urban group fell into this category. It is reasonable to assume that the male farm migrant would not have had money wage or salary earnings during the period of residence on farms in 1939 greater than 30 per cent of the amount he did or would have earned in an urban area. Consequently, I have assumed that the median earnings of the farm to urban migrants should be increased by a minimum of 10 per cent to adjust for the factor discussed here.[24]

The adjustment for the difference in age distribution was made by estimating the level of wage or salary income employed urban residents would have had if their age distribution had been the same as that of the farm migrants. This estimate was then subtracted from the earnings level reflected by the actual age distribution of the employed urban residents. The results of these adjustments are indicated in Table V.

Table V also provides a comparison between the adjusted wage or

[23] Sixteenth Census, *Population, The Labor Force (Sample Statistics)*, Wage or Salary Income in 1939, Table 10a.

[24] The method of arriving at this estimate may be indicated briefly. As noted in the text, 24 per cent of the migrants lived on farms part or all of 1939. If the movement occurred at the same rate during the 15 months through March, 1940, a fifth of this group of migrants would have lived all of 1939 on farms, while of the remaining four-fifths their average experience would have been a half year of work on farms and a half year of work (or seeking work) in urban areas. Thus taking the urban wage as one and the farm resident's salary or wage income as three-tenths, the following weighted average for all migrants is obtained:

$$\begin{array}{lcl} 0.76 \times 1.00 + & = & 0.760 \\ 0.048 \times 0.30 & = & 0.014 \\ 0.192 \times 0.65 & = & 0.124 \\ \hline & & 0.898 \end{array}$$

This average indicates that the actual wage or salary income of the migrant should be increased by about 11 per cent to adjust for the inclusion of income earned while a farm resident.

TABLE V.—MEDIAN ANNUAL WAGE OR SALARY INCOME OF EMPLOYED MALE RURAL FARM MIGRANTS TO URBAN AREAS AND OF EMPLOYED MALE URBAN RESIDENTS, AND ADJUSTMENTS FOR RESIDENCE AND AGE, CORN BELT AND COTTON BELT, 1939

Area and Color	Migrants' Median Wage or Salary Income[a] (dollars)	Residence Adjustment[b]	Age Adjustment[c]	Migrants' Adjusted Income (dollars)	Urban Median Wage or Salary Income[d]	Income Ratio: Migrants to Urban
Corn Belt, White	954	95	126	1,175	1,218	0.96
Cotton Belt						
South, White	690	69	122	881	1,010	0.87
North, White	708	71	134	913	1,040	0.88
South, Nonwhite	412	41	30	483	465	1.04
North, Nonwhite	404	40	50	494	465	1.06

[a] From special tabulations of Census data. Includes all employed workers on private or non-emergency government work in late March 1940, including those with no wage or salary income, but excludes any worker who had $50 or more of income from sources other than wages or salaries. The two standard deviation confidence limits for the sample medians, given in the same order as in the table are: 940–968, 670–710, 693–723, 394–430 and 386–422.

[b] An adjustment of 10 per cent applied.

[c] The age adjustment reflects the difference between the wage or salary level of the distribution of the employed migrants and of the employed urban residents evaluated at the level of earnings by age for the urban residents. For the white migrants, the age distribution and earnings levels by age were those for employed male urban residents for the United States as a whole. Source: Sixteenth Census, *Population, The Labor Force (Sample Statistics), Wage or Salary Income in 1939*, Table 6. For the nonwhite data from Sixteenth Census, *Population, Education, Educational Attainment by Economic Characteristics and Marital Status*, Tables 20 and 35, were used after minor adjustment.

[d] For wage or salary workers without other income on private and nonemergency government work. Median calculated for employed persons including those with no wage or salary income in 1939. For Corn Belt the income figure used is for the North Central States. (Sixteenth Census, *Wage or Salary Income in 1939*, Table 5). For the Cotton Belt, nonwhite, the South as defined by the Census is used (*ibid.*, Table I). The median wage and salary incomes for the two Cotton Belt areas were not available from the Census and it was necessary to estimate the medians. The median of $1,050 for white male employees for the South as a whole was reduced, in each of the two cases, by the percentage that the median family income for white wage or salary workers' families, in the states included in the Cotton Belt area, was below the similar median for the South as a whole. (See Sixteenth Census, *Population and Housing, Families, General Characteristics*, Tables 34 and 45.)

salary medians for the employed male farm migrants and the medians for urban employed workers. The results are, I believe, quite consistent with the estimate of a 10 per cent difference derived for the United States as a whole on the basis of the occupational distributions. Some of the variation in the ratios of the incomes are undoubtedly due to sampling variation. For example, the occupational distribution of the sample of Corn Belt migrants reflected an earnings value of about 3 per cent more than for all the farm to urban migrants from the North Central States. However, the combined occupational distribution for

all Cotton Belt migrants was virtually identical with that for the South as a whole.

The results are, I believe, reasonably consistent with the estimate of a 10 per cent difference in the labor capacities of the farm and nonfarm labor forces for the United States. The high relative incomes of nonwhite migrants in the Cotton Belt offset the somewhat lower relative incomes for whites in the same region. These data support one of the assumptions underlying the analysis of the occupational distributions, namely, that the farm migrants in any occupational group had the same median level of earnings as the urban resident in the same occupational group (after adjustment for age and sex). If this assumption were not valid, the relative money incomes derived from wage data would have been substantially below 90 per cent since the occupational distributions in our area samples were very similar to those for the regions that included the samples.

The data on money wages or salaries seem inconsistent with our earlier results at one point, namely, that the white labor forces in the Corn Belt and the Cotton Belt had the same labor capacities. This conclusion was based on the comparison of the occupational distribution, assuming that the levels of earnings by occupational groups were the same in the two areas. The data given in Table V on urban wage or salary incomes indicate that this assumption is not valid since the occupational distribution of nonfarm white workers in the South is nearly the same as for white workers in the nation as a whole.[25] Does the difference in the earnings of the urban residents in the South and in the North Central States reflect differences in the labor capacities of the nonfarm labor forces of the two regions? Though I cannot justify my conclusion in the space available to me, I would answer the question in the negative. Some of the difference can be explained in terms of the distribution of workers by size of community and size of plants in which workers are employed. Much of the remainder was due to the demand and supply relations in the labor market in the South compared to the rest of the nation. There is some evidence that there was a fairly substantial reduction in the labor-earnings differential between the South and the rest of the country from the late 'thirties to the late 'forties.[26]

Even if one accepts the assumption that the difference in labor earnings of urban residents does not reflect any difference in labor capacities,

[25] See D. Gale Johnson, "Some Effects of Region, Community Size, Color and Occupation on Family and Individual Income," *Studies in Income and Wealth*, Vol. XV (New York, National Bureau of Economic Research, 1952), p. 64. See also pp. 57-63 for a discussion of wages and labor earnings in the South compared to other regions.

[26] *Ibid.*, pp. 57-63.

there is a difference in the ratio of farm migrant and urban incomes in the Corn Belt and Cotton Belt.

It should be noted, however, that the occupational distribution of the Corn Belt migrants reflected an earnings value of about 3 per cent more than for all the farm to urban migrants from the North Central States, while the combined occupational distribution for all Cotton Belt migrants was virtually identical with that for the South as a whole. Thus if one reduced the ratio of migrant to urban incomes from 0.96 to 0.93, this might be a reasonable estimate for the North Central States as a whole. While the difference that remains of approximately five per cent in relative incomes after this adjustment is probably greater than can be explained by sampling errors, it does not seem unduly large given the other adjustments that have been made in the data.

The major surprise in the results is the nonwhite results. The consistency of results for the two samples creates doubt that the high ratio can be explained by sampling variability.

V. *Qualifications and Conclusions*

If the occupational experience and wage or salary income of recent migrants from farm to nonfarm areas can be used as an indication of labor capacity, and if farm migrants are representative of the parent farm population,[27] then farm people have a labor capacity approximately 90 per cent of nonfarm people of the same age and sex. Two main hypotheses are indicated in this summary statement and the conclusion obviously depends upon their acceptance.

I believe that the first of the hypotheses may be subject to some reservation. The occupational and wage experience of farm migrants in the first year or so following migration may underestimate the level of their labor capacities. Such an underestimate would occur if migrants tended to improve their occupational or income situation to a greater degree than the rate of advancement normally associated with age and experience. This proposition is one that can be put to empirical test and such a study is now under way.

It should be noted that in all analyses and calculations medians have been used instead of arithmetic means. However, we know that distributions of wage or salary data are not symmetrical, but exhibit an important degree of skewness, with the median less than the means. If the ratio of the mean to median were the same for all of the wage distributions used, it would make no difference in any of the results obtained in our analysis. However, though there is evidence that the ratio of the

[27] It is argued that the farm migrants are representative of the farm population only after adjustment is made for age and sex.

mean to the median is generally larger in the higher than in the lower-paying occupations, given the diversity within the broad occupational groups used by the Census, there is no systematic relationship between the mean and median as the median wage income rises.[28]

Though some doubt may be cast upon the accuracy of means calculated from open-ended distributions, comparisons were made using the calculated means as well as the medians in estimating the earnings value of occupational distributions. In every case the change in the results was very minor. For example, though the ratio of the income value of the occupational distribution of male farm migrants to urban areas to the same estimate for urban nonmigrants was slightly less when means rather than medians were used, the results when rounded to the nearest per cent were identical. In general the effect of using the estimated means rather than medians would not have changed the results given in Table III by more than one per cent.

The results obtained have several important empirical or practical applications, of which two may be noted quite briefly. One is the relevance of the results to comparisons of farm and nonfarm incomes, or more specifically, to comparisons of labor returns to farm and nonfarm workers.[29] Any comparisons of returns for large and relatively heterogeneous labor groups are always suspect, unless an effort is made to determine the relative equivalence of the labor capacities of the groups. The present results, however, should not be used directly without first standardizing the labor groups being compared for age and sex distributions. If this is done, it may well be found that the farm labor force has a larger proportion of its members in the age groups with lowest earnings. However, the effects of the unfavorable age distribution are likely to be largely offset by the relatively small proportion of females in the farm labor force compared to most other groups. Using 1940 urban wage distributions by age and sex as weights, the 1940 farm labor force had an earning capacity about 4 per cent below the nonfarm labor force. Thus, if real labor returns were as much as 14 per cent lower for the average farm worker than for the average nonfarm worker, this might well be consistent with equal real returns for comparable workers.

[28] Estimates of the mean for the seven nonfarm occupational groups for males were made from the available distributions. The ratios of the estimated mean to medians for experienced workers receiving more than $100 in 1939 were: (1) Proprietors, etc., 1.22; (2) professional and semi-professional, 1.20; (3) clerical and sales, 1.14; (4) craftsmen and foremen, 1.06; (5) operatives, 1.07; (6) service workers (excluding domestic), 1.18, and (7) laborers, 1.12. Source: Sixteenth Census, *Population*, Vol. III, *Labor Force*, Part I, Table 72.

[29] See L. H. Bean, "Are Farmers Getting Too Much?" and comments by D. Gale Johnson and J. D. Black, Rev. Econ. Stat., Aug., 1952, XXXIV, 248-61.

A second application of these results is the assurance that they provide to new employers who might wish to locate in areas of low farm incomes. The evidence indicates that such employers will find individuals having or capable of quickly achieving a wide range of skills. Only in the managerial and professional categories is it likely that new employers will have difficulty in recruiting a labor force roughly equivalent to that available almost anywhere in the United States. The evidence provided by the data for farm migrants is perfectly consistent with the favorable labor productivity experiences of many firms that have located in rural areas where farm incomes have been low.

FUTURES TRADING AND HEDGING

By HOLBROOK WORKING*

A good deal of difference of opinion on the utility of futures trading persists even among economists who have studied the subject rather closely. Some, at least, of this disagreement is traceable to imperfect concepts that emerged in connection with early academic studies of futures trading. Such concepts have tended to survive on the strength of their partial validity, despite shortcomings evident to the well-informed. Businessmen and others who are intimately acquainted with futures trading and its consequences tend to realize (often unconsciously) the defects of such imperfect concepts, to employ the concepts so far as they are valid and useful, and to avoid drawing any seriously mistaken conclusions from them. People who have little direct knowledge of futures trading and its observable results have no such protection against false inferences. If, like most economists, they are accustomed to rely on deductions from what seem to be well-established premises, they are especially vulnerable to the imperfections of basic concepts.

I. *Origin and Nature of Futures Trading*

Much of the popular suspicion of futures trading stems from a sense of mystery associated with it. It is in this respect, and some others, rather like bank credit. Futures trading, like banking, is an institution that developed as a contribution to efficiency of a relatively free competitive economy. A primitive form of futures trading emerged spontaneously in various market centers at least as early as 1850. Only in the grain trade at Chicago, however, was the demand for a means of hedging commercial risks then strong and persistent enough to permit this unconventional form of trade to survive the fluctuations in speculative interest, overcome conservative opposition, and live through the stormy period of experimentation necessary to put it on a firm footing. When that had been accomplished at Chicago, the new form of

* The author is associate director of the Food Research Institute, and professor of prices and statistics, Stanford University. This paper has been prepared under a research grant from the Merrill Foundation for Advancement of Financial Knowledge.

trading was soon adopted at other market centers and for other commodities than grains.[1]

Futures trading in commodities may be defined as *trading conducted under special regulations and conventions, more restrictive than those applied to any other class of commodity transactions, which serve primarily to facilitate hedging and speculation by promoting exceptional convenience and economy of the transactions.*

This may seem to some an inadequate definition. It does not say that futures trading is buying and selling for deferred delivery; it draws only a slender line of distinction between futures transactions and "cash" transactions (dealings in the "actual commodity"); and it makes the distinction between futures trading and other sorts of trading turn primarily on *purpose* rather than on more easily and objectively recognizable criteria. All of these characteristics are in fact merits of the definition.

It would be inaccurate to define futures trading as always involving purchase and sale for deferred delivery. Trading in the September wheat future, for example, is done in the month of September as well as in earlier months, and in that month it often happens that some sellers of September wheat intend to make immediate delivery, and the purchaser knows that he may expect to receive immediate delivery. The price of the future is then in fact a spot price. One might, of course, qualify the statement by saying that *most* futures trading is for deferred delivery. The statement would then be true, but objectionable in a definition because it would focus attention on a characteristic (deferred delivery) that has little distinguishing value. A great deal of buying and selling that is *not* futures trading involves delivery at some later time. In international commodity trade in staples, purchases calling for delivery two or three months or more in the future are commonplace, quite apart from true futures trading, and independently of whether or not futures trading exists in the commodity. Much of the trade in manufactured products as diverse as flour, steel rails, and machine tools (none of which has futures trading) involves purchase on contracts entered into several months in advance of the specified delivery date; in the case of machine tools, the interval may sometimes

[1] This, in two sentences, is the story that can be read from scattered comments in Charles H. Taylor, *History of the Board of Trade of the City of Chicago* (Chicago, 1917). Passages in Vol. I, pp. 146-47, 192, 217, 317 and 332, among others, cover the main developments through 1865, when the Board of Trade at last assumed responsibility for aiding and governing the conduct of futures trading.

H. C. Emery, in *Speculation on the Stock and Produce Exchanges of the United States* (New York, 1896) traces the history of trading that had at least some essential characteristics of that done in futures, from institution of the use of warrants by the East India Company in 1733 (p. 35), and says that "Futures were sold in some kinds of grain in Berlin by 1832, and some years earlier in France and Holland" (footnote, p. 41).

be measured in years. Because the people who turn for enlightenment to a definition of futures trading are often unaware of the wide prevalence of forward purchases (except in retail trade), the characterization "usually for deferred delivery" would fail to be generally recognized as only slightly narrowing the area of reference, and would divert attention from more sharply distinguishing characteristics.

The definition given above does in fact distinguish clearly between futures transactions and other transactions—so clearly that there need never be any problem of identification except in such cases as appeared when futures trading was taking its first steps in evolution from other trading and was not yet clearly differentiated. The definition lacks sharpness only in the sense that it does not make futures trading appear very different from other trading. That is a merit, because futures trading in fact has no distinguishing economic characteristics except those stated in the definition, or resulting from them (such as exceptional volume of trading, frequency of transactions, and publicity of quotations).

If a reader feels that the foregoing definition does not distinguish strongly enough between futures trading and other trading in commodities, it may be either because he underestimates the remarkable convenience and economy which are the primary distinguishing characteristics of futures trading, or because he mistakenly believes it to have peculiar characteristics that it does not have. Its extraordinary economy is illustrated by data cited below, in another connection, indicating that a trader in cotton futures could make a very satisfactory net income on the basis of a *gross* profit margin of about 23 cents per thousand dollars worth of transactions—a gross profit of one-fortieth of one per cent.

Mistaken impressions of the difference between futures trading and other trading have been furthered by a language difficulty that arises in connection with the frequent need to speak collectively of all-other-sorts of trading, as against futures trading. There is no good and convenient word for the purpose—and perhaps there cannot be, simply because the need is to designate all of a heterogeneous category except one special, narrow segment of it. "Nonfutures" would be an accurate and transparent term for the purpose, but an awkward one. In this situation, convenience has been served most commonly by using the word "cash" to mean "nonfutures." The practice probably originated in the Chicago grain trade, contemporaneously with the origin of sustained futures trading. Its application involved two shifts of meaning: (1) use of "cash" to designate, not immediate *payment*, as is usual, but immediate *delivery*; and (2) extension of the altered meaning to cover all terms of delivery except those involved in futures contracts. These

changes left the word with no logical merit for the purpose except its brevity. In the cotton trade, the common word for "nonfutures" is "spot." This is inherently more confusing than use of the term "cash," because "spot" continues to be used in the trade also in its specific sense of "immediate delivery"; but the grain trade has lost such potential relative advantage of clarity as it might have had, by using "cash" also as equivalent to "spot" in the sense of "immediate delivery."[2] Most seriously misleading is the frequent resort to use of "actual" to mean "nonfutures," as when purchases on terms other than those of futures contracts are distinguished as purchases of the "actual commodity." That expression is used to *include* forward purchases other than on futures contracts, even though all forward purchases are alike in the fact that there is no acquisition of the actual commodity at the time of purchase.[3] Like the other expressions used for the same purpose, it is a verbal expedient only vaguely defensible in terms of the normal meaning of the expression. Futures contracts involve transactions in the actual commodity as truly as do any other forward transactions.

As regards failure of the definition to give easily and objectively recognizable criteria for identifying futures trading, it should be noted that there is no practical problem of identification except in cases of primitive futures trading, and in such cases purpose is the only available criterion;[4] otherwise, futures trading has always gone under that name, or the equivalent in another language. The definition should indicate the essential distinguishing nature of futures trading, and that is not done by mere listing of superficial technical characteristics, specified in regulations intended to promote convenience and economy. Reliance on these superficial characteristics for definition encounters also the difficulty that they have varied widely from time to time and from place to place. Consequently, definitions based on such characteristics show an historical trend toward increasing complexity and obscurity as later writers tried to remedy technical shortcomings found in earlier definitions.[5]

[2] This is not to say that anybody in either the cotton or the grain trade *is* confused by these practices any more than initiates are confused by the colloquial uses of "buck," "date," and "doll" (all words with the same brevity as "cash" and "spot"); but the usage is a bit frustrating, and even misleading, to an inquiring novice.

[3] Whether use of the expression has its foundation directly in this characteristic, or in the related fact that *speculators* use futures contracts, as they may any forward contracts, to avoid necessity for *handling* of the actual commodity, is a matter of surmise.

[4] The characteristics of convenience and economy being at that stage not well developed.

[5] See, for example, the evolution of definitions from H. C. Emery, *op. cit.*, p. 46, through J. G. Smith, *Organized Produce Markets* (London, 1922), p. 44; C. O. Hardy, *Risk and Risk Bearing* (Chicago, 1923), pp. 205-06; J. B. Baer and O. G. Saxon, *Commodity Exchanges and Futures Trading* (New York, 1949), pp. 132-34.

II. *Hedging as a Basis for Futures Trading*

An interesting conflict of evidence has emerged regarding the comparative rôles of speculation and hedging in sustaining futures trading. Most of the available information prior to about 1920 encourages the view that futures trading rests primarily on an urge for speculation. Hedging is rarely mentioned except in arguments justifying the continuation of futures trading. One gains the impression that hedging, like a hitchhiker, seized the chance for a ride since speculation presented the opportunity. But as statistics have been accumulated that give appropriate quantitative information on futures markets, year in and year out, hedging begins to look like the driver, and speculation in futures like a companion going where hedging gives it opportunity to go.

The first conspicuous evidence in this direction came in studies of the Grain Futures Administration (predecessor of the present Commodity Exchange Authority) that showed the volume of open (outstanding) futures contracts in each commodity rising and falling each year in rough correspondence with the volume of the commodity in commercial hands and likely to be hedged.[6] Speculators tend to be most heavily committed in futures, not during the growing season of a crop, when prices are most variable, but some time after harvest, when large stocks have moved into commercial storage and been hedged.

As between commodities, the volume of open contracts varies likewise with the amount of the commodity that is hedged. The volume of open contracts in wheat futures in the United States during recent years has averaged about 90 million bushels, while the volume in corn futures has averaged not much over 50 million, though corn has been produced in nearly three times the volume of wheat. The reason is that much less corn than wheat gets into commercial hands (farmers rarely or never hedge the stocks that they hold). Oats, produced in volume less than half that of corn and, like corn, stored mainly on farms, has had an average volume of open futures contracts less than half that of corn.[7] So one may go through the list of commodities in which there is futures trading and find, wherever there is information on the amount of hedging use of futures markets, an unmistakable connection between size of the futures market and the amount of hedging that the market is called on to carry.[8]

[6] See, for example, the summary of much earlier work in G. Wright Hoffman, *Grain Prices and the Futures Market*, U. S. Dept. Agric., Tech. Bull. No. 747, January 1941, pp. 33-38.

[7] Data are conveniently available in *Agricultural Statistics* (Washington) for any recent year.

[8] Size of a futures market is better judged by volume of open contracts than by volume of trading because of the wide variation between markets in proportion of trading con-

Though the amount of speculation on a futures market seems to depend so much on the volume of hedging, there is also a connection in the other direction. As between different exchanges dealing in the same commodity, there is a strong tendency for hedgers to prefer to use the exchange which has the largest volume of speculative trading. We shall examine the reason for this later. As regards commodities, it may be observed that in some the volume of hedging has, at times at least, been restricted by absence of sufficient speculative interest to carry the hedges.[9] In the United States, no futures market for a commodity which is chiefly imported, has flourished like the markets for the more important domestically produced commodities. This may be not entirely because the imported commodities give less occasion for hedging, but partly because there are relatively few people in the United States who have acquired an interest in those commodities sufficient to inspire speculation in them.

When one reviews evidence on the earlier history of futures trading, making allowance for the tendency for sporadic news and comment to concentrate on the unusual, and for exceptional outbursts of speculation to draw special attention, one can find reason to think that a desire for hedging opportunities may have always provided the primary support for futures trading. It seems reasonable to suppose that a primitive form of futures trading in grains was able to survive and develop to maturity in Chicago in the middle of the last century, whereas similar trading tried somewhat earlier in Europe was abandoned, because there was much more occasion for hedging the large stocks of grain that came into commercial hands in the Chicago area than for hedging the much smaller stocks of European markets. It seems quite clear that the first successful futures trading in wheat in Great Britain was based on contracts for Californian wheat because that was the wheat which importers found most need to hedge, on account of the long periods over which importers held ownership while the wheat travelled by sailing vessel around Cape Horn to Britain.[10]

One can imagine existence of futures trading purely on the basis

tributed by "scalping" and by other trading that involves holding a commitment for only a few minutes or hours, with correspondingly small speculative risk and small economic significance.

[9] For example, such an inference seems to follow from information in Blair Stewart, *Trading in Wool Top Futures*, U. S. Dept. Agric., Circ. No. 604, August 1941, pp. 16-26.

[10] See Holbrook Working and Sidney Hoos, "Wheat Futures Prices and Trading at Liverpool since 1886," *Wheat Studies of the Food Research Institute* (Nov. 1938), XV, 125, 142-44. I would now attach less importance than is done there to the uniformity of the quality of the Californian wheat, judging that factor to have been important mainly in the preference for the Californian over the Indian wheat contracts, in which also there was effort for a time to maintain futures trading.

of desire of people to speculate; but apparently futures trading cannot long persist except on the basis of conditions that create speculative risks which somebody must carry, and which some people are led to transfer to others by hedging. The reasons for choosing thus to transfer risks deserve our attention next.

III. *Misapprehensions about Hedging*

It is common to suppose that hedgers exercise no part in determining the price of the commodity in which they deal, and this supposition is substantially valid as regards those who practice hedging uniformly.[11] But most hedgers are engaged in a business that requires them to keep informed on many aspects of the commodity situation, with the result that many hedgers often form quite definite opinions on price prospects. Except in firms that have a strict rule against taking hedgable risks, it is common, therefore, for stocks to be carried unhedged at times, when the responsible individual expects a price advance, and for stocks of the commodity to be hedged at other times. Some individuals and firms hedge stocks only when they are particularly fearful of price decline.

Such discretionary hedging, involving a firm in the practice of both hedging and speculation, seems to be especially prevalent among dealers and processors who handle commodities such as wool and coffee, that have relatively little public speculation in their futures markets.[12] When hedge selling in such a futures market becomes heavy, the price may readily be depressed to a point where a good many dealers and processors are attracted by the possibilities of profit through speculative holding of the commodity. Even among handlers of commodities which attract broad public participation to their futures markets, such as wheat, discretionary hedging is not uncommon.[13] Consequently the existence of futures trading in a commodity and widespread use of futures for hedging do not in fact mean that the responsibilities of price formation are shifted entirely, or even mainly, to people who deal only in the commodity futures.

A major source of mistaken notions of hedging is the conventional practice of illustrating hedging with a hypothetical example in which

[11] Not entirely valid because hedgers are the active agents in determining the *relation* of spot to futures prices, and to that extent they play a major rôle in formation of the spot price.

[12] The case of wool has been documented (*cf.* Blair Stewart, *op. cit.*); the inference that similar situations exist in certain other commodities is based on fairly reliable trade reports.

[13] *Cf.* the Federal Trade Commission's *Report on the Grain Trade* (Washington), Vol. I (1920), pp. 213-27; and Vol. VII (1926), pp. 38-57; and Holbrook Working, "Financial Results of Speculative Holding of Wheat," *Wheat Studies* (July 1931), VII, 417-28.

the price of the future bought or sold as a hedge is supposed to rise or fall by the same amount that the spot price rises or falls. Let us instead consider hedging realistically in terms of some actual prices. The prices to be used will be those for wheat at Kansas City on the first trading day of each month in which futures matured during the crop-year 1951-52.[14]

On the first business day of July 1951, a merchant or processor[15] considering the purchase of the cheapest quality No. 2 Hard Winter wheat (the quality represented by quotations on Kansas City wheat futures) found such spot wheat selling at 3 cents per bushel under the price of the September future. If he bought spot wheat, hedged it in the September future, and carried the wheat until the first business day of September, the results, in cents per bushel, would have been as shown below:

Quotation	Date and Price		Gain or Loss
	July 2	Sept. 4	
Spot No. 2 Hard (low)	$229\frac{1}{4}$	$232\frac{1}{2}$	......
September future	$232\frac{1}{4}$	$233\frac{1}{2}$	......
Spot premium	−3	−1	+2 (gain)

The profit of 2 cents per bushel is calculated above, in what may seem an awkward way, from the change in spot premium (a negative premium, or discount, on each of these dates). It is awkward, however, only for those to whom it is unfamiliar. The hedger tends to calculate his profits in this way because he would buy the wheat on July 2 primarily for the reason that he could get it at discount of 3 cents per bushel under the price of the September future. In fact, the bargaining which preceded the purchase would normally proceed in terms of discount rather than of price, the price being ascertained by reference to the latest futures price quotation, after sale at a mutually satisfactory discount had been agreed on.[16]

[14] Kansas City is used rather than Chicago because changes in the major wheat-producing areas and in the normal lines of movement of the commodity have left Chicago with a vestigial spot wheat market that no longer affords a good source of spot price quotations.

[15] The case of a merchant or processor deserves to be considered rather than that of someone not in such a business, who might buy merely for storage, because merchants and processors gain auxiliary benefits from having stocks on hand that give them a competitive advantage in storing. Their competition for the returns available from storage leaves little opportunity for profitable storing as an independent enterprise.

[16] This is the normal procedure in connection with spot sales of wheat at Kansas City and at other markets with active futures trading. The actual bargaining on July 2, however, would have been in terms of premium or discount in relation to the price of

The fact that on September 4, No. 2 Hard Winter wheat sold at a discount under the September future, though it is the grade of wheat currently deliverable on the future, is accounted for by the fact that the spot price applies to wheat "on track," requiring additional expenditure to get it into a warehouse.[17] Wheat was then moving into commercial storage on a large scale because of heavy marketing by producers.

On September 4, our grain merchant or processor would probably not have sold the wheat he bought earlier, but instead would have bought more wheat. If he did that, and held until December 1, the results, in cents per bushel, would have appeared as follows:

Quotation	Date and Price Sept. 4	Dec. 1	Gain or Loss
Spot No. 2 Hard (low)	252½	252	......
December future	258¼	252	......
Spot premium	−5¾	0	+5¾ (gain)

In this case the spot price of the cheapest deliverable wheat came, on December 1, to exact equality with the price of the December future, and the gross return for storing the wheat was exactly what might have been expected, on September 4, from the fact that such wheat was then selling at a discount of 5¾ cents under the price of the December future.

the *July* future, the prospective hedger bearing in mind the prevailing discount of the July future under the September.

Since the gain or loss from hedging calculated in such tabulations as that in the text above depends only on the spot premiums, the prices included in the tabulations are no more than interesting collateral information. The spot premium or discount for a specified quality of the commodity rarely changes much during the course of a day or even a week. With regard to the futures prices, however, it is pertinent to note the time of day. Those used here are the closing prices for the day. The spot prices are closing prices of the future currently being used as a basis for spot sales, plus the quoted premium for lowest quality No. 2 Hard Winter wheat. The source is the Kansas City *Grain Market Review,* which quotes also daily high and low spot prices for the various grades, in which the low quotation for each grade is obtained by adding the premium for lowest quality wheat in that grade to the lowest price of the future for that day.

[17] Sometimes the spot price on track in a delivery month falls to a considerable discount under the near future because of lack of warehouse space for economical storage. The spot price on track tends to be at a *discount* under the price of a current-month future, which is then also effectively a spot price, when the prevailing direction of movement of the commodity is into storage; it tends to stand at a premium over the future when the prevailing direction of movement is out of storage. Moreover, the spot quotations for the cheapest wheat of deliverable grade may represent wheat of slightly better quality than that which will be delivered on futures contracts. To be graded No. 2, wheat must meet all of several requirements; the wheat delivered on futures contracts may be at or near the minimum in all respects when the cheapest wheat on which spot quotations are available is close to the minimum in only one of the grade requirements.

In these calculations we have left out of account the possibility that a merchant who bought at a discount of 5¾ cents on September 4 might have got wheat of a little better than minimum No. 2 quality—wheat which might have been sold on September 4 at a discount of, say, 5½ cents, rather than 5¾ cents, if the seller had been willing to look farther for a buyer. And we have ignored the possibility that on December 1 the merchant might have sold at a premium of ½ cent over the December future by virtue of the slightly superior quality of the wheat, and by finding a buyer who did not choose to shop around enough to get the best bargain possible. In other words, we have left out of account sources of normal *merchandising* profits.

On December 1 a merchant or processor may seem to have had no incentive for longer holding of wheat for which he had no immediate need. The spot price then was on a par with the December future, and at a premium of 1 cent over the price of the May future. But let us suppose that he continued to hold, with a hedge in the May future, and see what would have happened if he held until May 1. Though we imagine that the wheat is already in storage, we may make the next calculation as though it concerned a new purchase:

Quotation	Date and Price Dec. 1	May 1	Gain or Loss
Spot No. 2 Hard (low)	252	247¼	......
May future	261	238¼	......
Spot premium	+1	+9	+8 (gain)

This time a merchant would have gained a gross return of 8 cents per bushel from storage. It would have been in part a windfall profit, since he had no advance *assurance* of obtaining it; but he would have gained it on a quite conservative venture. He was well assured of not losing more than 1 cent per bushel (because the spot wheat that he held would surely sell at as high a price as the May future at some time in May), and he could count with virtual certainty on spot wheat going to a substantial premium over the price of the May future at some time between December and May.[18]

As of May 1, there remained no prospect of profit from continued storage of wheat during that crop-year, unless perhaps for a few days more. Before the end of the month, the spot premium, based on the

[18] One of the indications of this prospect was the fact that spot wheat had already reached a premium of 1 cent over the May future by December 1. The cause, of which any holder of large wheat stocks would have been well aware, was the holding by growers of some 300 million bushels or more under nonrecourse loans offered by the Commodity Credit Corporation.

May future, would have to fall from 9 cents to near zero.[19] Moreover, the spot price on May 1 was at a premium of 18 cents over the July future, and that premium should be expected to fall to zero or below by July 1. The outcome, if a merchant in fact held any wheat in storage from May 1 to July 1, was as follows:

Quotation	Date and Price May 1	July 1	Gain or Loss
Spot No. 2 Hard (low)	247¼	218¾	......
July future	229¼	225	......
Spot premium	+18	−6½	−24½ (loss)

Probably some merchants did store a little wheat from May 1 to July 1, hedged in the July future, and did take the loss per bushel indicated by the above calculation. Grain merchants, like operators of retail stores, must try to keep adequate stocks on their shelves to serve their customers. But a merchant who hedged would have seen clearly on May 1 that any wheat that he might continue to hold until July would involve a loss, as surely, though not so completely, as would Christmas trees held until December 26.

The foregoing examples of hedging tend in one respect to be a little misleading; spot premiums do not always follow so obviously logical a pattern through the course of a crop year as they did in 1951-52. If spot wheat in July, were regularly, in all years, at a moderate discount under the September future, and if spot wheat, in September, were always at a large discount under the December future, and spot wheat in May always at a large premium over the July future, merchants and processors would have less need than they do for futures markets.[20] They would then have no need to watch spot-future price relations in order to judge when to accumulate stocks, and when to draw them low. But our purpose at the moment is merely to see how hedgers use spot-

[19] Not necessarily to zero, because deliveries on futures contracts would consist of wheat in public elevators; in May, wheat on track tends to be worth more than the same quality of wheat in a public elevator because it is already loaded in a freight car and ready to be moved to wherever it is wanted.

[20] When spot wheat in May is at a premium over the July future, it is not because the new wheat crop—coming to market in large volume by July—is expected to be large, but because current supplies of old wheat are scarce. (In May 1952 the scarcity applied only to commercially available supplies, being a result of the large holdings of wheat by the Commodity Credit Corporation in connection with its price-support operations.) On the subject of "inverted" intertemporal price relations in general, see Holbrook Working, "Theory of the Inverse Carrying Charge in Futures Markets," *Jour. Farm Econ.* (Feb. 1948), XXX, 1-28; "Professor Vaile and the Theory of Inverse Carrying Charges," *Jour. Farm Econ.* (Feb. 1949), XXXI, 168-72; and "The Theory of Price of Storage," *Am. Econ. Rev.* (Dec. 1949), XXXIX, 1254-62.

futures price relations as a guide in inventory control, thereby earning a return for holding stocks that must be stored by someone. We may reasonably avoid being led here into discussion of the frequent effects on spot premiums produced by exceptional export demand, by governmental price supports, or by unusual holding disposition on the part of producers.

We should now note three facts concerning hedging. First, contrary to a common impression, hedging of the sort here considered is not properly comparable with insurance. It is a sort of arbitrage. We shall consider later an example of conditions under which hedging may in fact be profitably compared with insurance, but such conditions obtain for only a small proportion of the hedging that is done on futures markets. Most hedging is done in the expectation of a change in spot-future price relations, the change that is reasonably to be expected being often indicated quite clearly by the current spot-future price relation.

Secondly, hedging does not eliminate risks arising from price variability. Risk is less than on stocks held unhedged, but it still exists. When the commodity involved is of quite different quality than that represented by the future, or in a location remote from that to which the futures price relates, the risks assumed by hedgers tend to be much larger than is suggested by the examples given here.

And thirdly, hedging is not necessarily done for the sake of reducing risks. The rôle of risk-avoidance in most commercial hedging has been greatly overemphasized in economic discussions. Most hedging is done largely, and may be done wholly, because the information on which the merchant or processor acts leads logically to hedging. He buys the spot commodity because the spot price is low *relative to* the futures price and he has reason to expect the spot premium to advance; therefore he buys spot *and* sells the future. Or in the case of a flour miller, he sells flour for forward delivery because he can get a price that is favorable *in relation to* the price of the appropriate wheat future; therefore he sells flour *and* buys wheat futures. (Here the arbitrage, it may be noted, is between two forward prices, that for flour and that for wheat.)[21]

Incidentallly, recognition of the fact that hedging may be done purely as a logical consequence of the reasoning on which the hedger acts (reasoning, for example, that the spot price is low relative to the

[21] Two instructive explanations of hedging written by hedgers themselves, such as are not often found, are: Ellis D. English, "The Use of the Commodity Exchange by Millers," *Proceedings, Fifth Annual Symposium* (Chicago Board of Trade, 1952, mimeo.) pp. 22-29; Virgil A. Wiese, "Use of Commodity Exchanges by Local Grain Marketing Organizations," *ibid*, pp. 108-16.

future) rather than from any special desire to minimize risks, helps to explain why many dealers and processors sometimes hedge and sometimes do not. As we have remarked, merchants and processors, even though they hedge, have need to keep informed on conditions that affect the price of the commodity and they may often have opinions on prospective price changes. If a merchant is accumulating stocks at a time when spot premiums are low—his most reliable basis for such action—and if at the same time he is fairly confident of an advance in futures prices as well as in spot premiums, why should he not carry the stocks unhedged, if he can afford to take some extra risk?

Perhaps the main reason that hedging, as commonly practiced on futures markets, has been so widely misunderstood and misrepresented is that economists have tried to deal with it in terms of a concept that seemed to cover all sorts of hedging. This would be desirable if it were feasible, but the general concept of hedging as taking offsetting risks wholly, or even primarily, for the sake of reducing net risk, serves so badly as applied to most hedging on futures markets that we need another concept for that most common sort of hedging. To put it briefly, we may say that hedging in commodity futures involves the *purchase or sale of futures in conjunction with another commitment, usually in the expectation of a favorable change in the relation between spot and futures prices.*

An unfortunate consequence of the prevalent misconception of hedging has been that, while it has correctly credited futures markets with allowing merchants and processors to curtail their risks, it has diverted attention from a service of probably larger economic importance. Merely by supplying simultaneous quotations applying to various subsequent dates, futures trading tends to promote economically desirable control of stocks; and futures markets, through their use for hedging, make the holder of stocks sharply aware of any losses that must be expected from carrying unnecessary stocks in times of relative shortage of supplies, and provide assured[22] returns for storage over periods when there is a surplus to be carried. A merchant or processor with warehouse facilities will undertake storage in response to prospect of a 10-cent per bushel gain from carrying hedged stocks about as readily as he will undertake storage in response to an offer of 10 cents per bushel as a fee for storing government-owned grain. Indeed he may undertake storage for the return promised by hedging more willingly than for the fee, because the stocks that he holds hedged need be carried only as long as he wishes, and can be a source of convenience or of profit in connection with his merchandising or processing business. The argu-

[22] Though subject to some risk, as we have seen.

ment often made that management of reserve stocks of commodities should be a governmental function rests in large part on ignorance of the effectiveness with which the hedging facilities of futures markets assure private carrying of stocks in about as large a volume as can be justified on purely economic grounds.[23]

The claim sometimes made by able economists[24] that prices of such storable commodities as wheat, corn, and cotton fluctuate excessively because stocks are accumulated at wrong times, and not accumulated when they should be, seems also a consequence, indirectly, of the prevalent misconception of hedging. Mismanagement of stocks by nonhedgers would have to be on a very large scale to produce an over-all tendency toward perverse stockholding in any commodity with a futures market much used for hedging.[25]

IV. *Price Fluctuations*

Futures trading tends to emerge and persist especially in commodities which are subject to exceptionally large price fluctuations, arising from unpredictable variations in production, from other supply uncertainties, and from relative inelasticity of consumption demand.[26] Susceptibility of a price to large and unpredictable changes tends to stimulate hedging, and therefore futures trading, whether handlers of the commodity seek insurance against the risks of price change, or are led into hedging merely because they find spot premiums a more reliable guide to inventory control than are the prices themselves. (The relative superiority of spot premiums as such a guide depends of course on the price variability.) On this account, the fact that prices of commodities which have

[23] If considerations of national defense warrant the carrying of commercially uneconomic stocks of a commodity, government should of course assume the responsibility and the financial burden of carrying such excess stocks.

[24] For example, T. W. Schultz in *Production and Welfare of Agriculture* (New York, 1949), pp. 172-74.

[25] The hypothesis of perversity of stockholding tendencies is not supported by any statistics that I know, but is contradicted by them. Of particular interest is the fact that in the years when one could speak realistically of a world wheat market, the countries in which year-end (June 30) stocks of wheat varied in rational correspondence with world wheat supplies were the countries where hedging was practiced on a substantial scale. In most countries, year-end stocks of wheat varied little, and primarily with size of the previous *domestic* crop. Britain, with a futures market but with only small storage facilities, contributed little to the carrying of world wheat surpluses. Canada contributed more; and the country which most consistently carried large stocks at the end of any year of world wheat surplus, and reduced stocks to a minimum in times of world wheat shortage, was the United States. *Cf.* Holbrook Working, "The Changing World Wheat Situation," *Wheat Studies* (Sept. 1930), VII, 433-52.

[26] No reference is made here to changes in demand as a cause of *exceptional* price variability, because those demand changes which contribute to price instability of staple commodities are mainly of the sort that affect all sensitive prices similarly.

futures trading are found to be more variable than most other prices gives no ground for supposing that futures trading is a *cause* of the exceptional price variability.[27] It is none the less pertinent to raise the question whether existence of futures trading has a stabilizing or destabilizing influence on prices, and to seek some objective evidence on the question.

The results of attempts to determine whether prices of commodities that have futures trading fluctuate more or less than they would in the absence of futures trading have been generally inconclusive. Even if clear proof were given that futures trading tended somewhat to restrict price fluctuations, it might still be true that futures prices fluctuate too much. Some criterion is needed for an absolute test by which to determine whether the price fluctuations that occur are excessive, or are, in the main, rational and desirable responses to changing economic conditions and information.

A few years ago I suggested that such a test might be developed from the consideration that prices of durable goods (and especially futures prices) reflect expectations.[28] These expectations are always subject to error, but the errors of expectation might, in an *ideal* market, be only such as must arise from uncertainties inherent in the economic situation. That is, the price of May wheat, for example, might fluctuate, and yet be always the best estimate that could be made at the moment of what the price of wheat should be next May. *Excessive* price fluctuations might be measurable as the amount of fluctuation that occurred over and above the amount attributable to unpredictable changes in the economic situation. Unpredictability of change would thus be taken as the ideal in price behavior.

This idea has been pursued, and appropriate statistical methods have been devised for making the suggested tests.[29] For technical reasons the new approach to the problem of testing price behavior has been applied first to appraisal of the frequent and sometimes large price fluctuations that occur on active futures markets during the course of a day. The results indicate some departure of actual price behavior from the ideal, as was to have been expected, but only slight departures; the observed

[27] It appears sometimes to be so taken nevertheless, even by economists who would be expected to see the fallacy of such an inference.

[28] "The Investigation of Economic Expectations," *Papers and Proceedings, Am. Econ. Rev.* (May 1949), XXXIX, 158 ff.

[29] The tests involve in principle the measurement of serial correlation among price *changes,* which in practice must be present to some extent if price changes are predictable (that this is so may seem obvious, but the proof requires more space than is available here). The statistical measures used have been especially devised to be more sensitive than serial correlation coefficients to the sorts of departure from randomness of change that are to be expected in price series. They have also an advantage of economy in use.

price fluctuations were for the most part such as should occur purely from unpredictable changes in price prospects.[30]

In an ideal futures market in which the price of May wheat, for example, was at all times the best possible estimate of what the price would be next May, no speculator would be able to consistently make money, and the speculation necessary to maintain even an approximation to ideal price behavior would tend to vanish. Speculative profits that are not purely the result of chance must rest on ability to anticipate price changes with some degree of reliability, whereas if a futures price were always the best possible estimate of price at a later date, its changes would be entirely unpredictable.[31] Since many professional traders do make money in actual markets with some degree of consistency, it is evident that they are able to anticipate price changes with some approach to reliability and hence that the price behavior is not ideal. Study of the nature of the price fluctuations that professional traders are able to anticipate may therefore give the best clue to the nature of the imperfections of actual speculative markets—the predictable price fluctuations that would be absent in an ideal futures market, but that are present in actual markets.

Perhaps the largest class of professional traders is that of "day traders"—those who operate primarily on intraday price fluctuations, and who end each day neither net long nor net short in appreciable amount.[32] One such trader in cotton had the following record over a two-month period chosen substantially at random.[33]

Month	Number of Transactions[a]		Average Daily Sales (million pounds)	Gross Profit[b]		Number of days with	
	Total	Per day		Cents per lb.	Per-cent	Gain	Loss
February	1701	77.4	4.9	.0167	.042	15	7
March	1343	64.0	4.2	(c)	(c)	13	8
Total	3044	70.8	4.6	.0093	.023	28	15

[a] Purchases and sales.
[b] Per pound or per dollar of sales.
[c] Infinitesimal; a gross profit of $187.00 on $35 million of sales.

[30] The relative amount of departure from ideal behavior has been measured numerically, but it is not possible to summarize the results meaningfully in brief.

[31] Price changes would always be consequences of new information, unavailable as a basis for prediction before the price change occurred.

[32] Professional traders specialize to such an extent as to make classification meaningful, and the intraday traders especially tend to concentrate on one type of trading.

[33] The record was obtained for this individual because he was regarded as a representative, successful, day trader. The period was simply the two months ending at the time (in 1952) when he was interviewed.

During the two months of the record, this man averaged nearly 70 trades per day, which is at the rate of about one every four minutes. His purchases were not bunched during the parts of the day when prices were low, nor his sales bunched during the parts of the day when prices were high, but purchases and sales were distributed throughout the price range of the day.[34] He made money simply by managing to have his purchases, on the average, at prices a little lower than the prices of his sales. On the days on which he made money, his gross profits averaged 1/30 cent per pound. Since the cotton price was about 39 cents per pound, his gross profit on the days when he made money was about 82 cents per thousand dollars worth of cotton that he bought and sold. Net profits, after paying commissions and other business expenses, were substantially less.

The gross profits calculated above are on trading during only the 28 days out of 43 on which he made money. On 15 out of 43 trading days during the two months, he lost money. Such a result might not be surprising in the case of a man who made only a few trades each day, but 70 trades per day—about 35 purchases and 35 sales—gave much opportunity for successes and errors to offset within a day. Nevertheless, he lost money on more than one day out of three, on the average. This is not the sort of experience that most people imagine successful professional traders as having.

Because profits were so uncertain and variable, a calculation of the average rate of profit of this trader over even a two-month period may not give a very reliable indication of the normal profit expectation for such a trader. The figures, for whatever they may be worth, show that in the first of the two months his gross profit averaged 1/60 cent per pound; in the second of the two months, losses nearly equalled gains—his total gross profit for the month would not have covered the commission charges he often paid on a single day's trading. For the two months together, his gross profits averaged about 23 cents per thousand dollars worth of cotton sold—less than one-fortieth of one per cent. Doing such business, he could make a living only by dealing in great quantities of the commodity; he bought and sold an average of over nine thousand bales of cotton—4.6 million pounds—per day.[35]

Another day trader, who was not primarily a true scalper, but sought principally to trade on larger price fluctuations within a day than those

[34] This was ascertained by separately tabulating purchases and sales each day in frequency distributions according to price.

[35] Incidentally, the fact that a gross profit of 23 cents per thousand dollars worth of purchases and sales could permit any net profit at all is striking evidence of the main technical characteristic of futures trading, the economy with which transactions can be made.

on which pure scalpers operate, found that his gross profits during the previous seven months, on the Chicago Board of Trade, averaged 70 cents per thousand dollars of sales—seven hundredths of one per cent. The period beginning with January 1952 was one which he described as especially successful. Giving particular attention, as he did, to somewhat larger price fluctuations than occupy the pure scalper, he made relatively few trades per day in any one commodity, but a considerable total number because on most days he did trading in five or six different commodities.[36]

One might seek to get a large number of records such as those summarized above, and for longer periods, in order to arrive at a conclusion regarding *typical* behavior and profits of day traders, but it is clear from this and other evidence, that the typical day trader and his profits would prove about as elusive as the typical insurance salesman and his income. These records, by themselves, serve as warning that some popular concepts of the manner in which professional traders operate, and of the sources of their profits, may be quite mistaken. With other and more detailed records, they give valuable aid in interpreting results of statistical measurements of price behavior, made on the principle outlined above.[37] All of the evidence converges toward the conclusions that: (1) the price movements that day traders are able to anticipate with even moderate reliability are usually small relative to the total price range for the day; (2) the reliability of their judgment is rather low; and (3) the over-all effect of their trading operates strongly toward "smoothing" the course of prices, helping to make intraday price fluctuations conform closely to our criterion of ideal behavior.

These conclusions bear directly on the question whether the price fluctuations that occur in futures markets within the day tend to be excessive or not. The question is not inherently a very important one because, though price fluctuations in the two months of the illustration covering cotton resulted in an average difference of 0.4 cent per pound between the lowest price and the highest price each day, it would not matter greatly if fluctuations of such magnitude did occur without good reason. The conclusions reached are more important than the specific question to which they apply, because they indicate reasonableness in just that trading and those price fluctuations which may be thought most likely to be unwarranted.

On the question whether the larger price fluctuations that occur over longer periods are in the main warranted, the best evidence that I

[36] A feat comparable to that of playing several games of chess simultaneously, blindfolded.

[37] A full report on the research will be published shortly.

can yet cite[38] is essentially subjective and inconclusive. It is the evidence which led me to question the common assumption, and to try to measure the amount of "excessive" fluctuation that is present in "speculative" prices. During the twenty years of publication of *Wheat Studies* by the Food Research Institute, members of the research staff periodically studied the recent fluctuations of wheat prices and sought to interpret them as warranted by current developments, or unwarranted. For much of that period we sought three times a year to appraise price prospects for the next several months. Everyone concerned with these efforts gained a great respect for the rationality of the price behavior observed. During twenty years some price movements occurred which it seemed possible to appraise at the time as ill-founded or excessive, but these were exceptional. Only rarely did it seem possible to anticipate subsequent price movements with confidence on the ground that the current price appeared unjustifiably high or low.

As regards price changes from year to year, it is entirely clear, as noted in the previous section, that futures markets contribute substantially toward desirable adjustment of stocks carried from one year to another. Whether or not they produce as much flexibility of storage as is desirable they at least operate in that direction.

V. *Costs of Hedging*

We turn now from topics on which there has existed major disagreement, springing largely from imperfect or mistaken concepts, to examine a new, or at least largely neglected, idea that illuminates hitherto obscure aspects of futures trading. The idea came to me through puzzling over two questions:[39] Why does futures trading in a commodity tend to concentrate largely or wholly in one exchange? And why is futures trading on any one exchange usually confined to a single set of contract specifications for a commodity, rather than distributed among several contracts, representing different qualities of the commodity? Hedgers, it may seem, would be best served by having numerous futures exchanges, and several different futures contracts in each, so that hedges could be placed always in a future that applied to a quality of the commodity corresponding closely with that being hedged, and to a location at or near that of the hedged stocks. The answer seems to lie in a cost of hedging.[40]

[38] Pending completion of research under way.

[39] And also from what we learned in the study of intraday price behavior referred to above.

[40] I thought at first that the answer lay in a somewhat capricious behavior of speculators, coupled with a necessity for hedgers to use those exchanges and contracts in which there was sufficient speculation to carry the hedges. But, when this argument was advanced in a paper dealing with a special case ("Western Needs for Futures Markets," mimeo., Food Research Institute, 1952) it drew objections that seem fatal.

There are at least two significant elements to be considered as parts of the cost of hedging.[41] The most obvious one is the commission charge that must be paid on futures transactions.[42] Futures trading must operate with great efficiency to keep this charge so low as not to discourage hedging seriously, since much of the advantage that a hedger gains, as we have seen, comes from a guidance in inventory control that is available without actually placing hedges. In addition to commissions, there is a cost of hedging that can be much larger, arising from what may be called the bivalence[43] of market price. The contribution of price bivalence to costs of hedging declines sharply, as we shall see, with increase in the volume of business done on an exchange, and it declines also with increase in the volume of business in a particular futures contract. It has, therefore, just the characteristics needed to explain observed tendencies in the concentration of futures trading.

Our awareness of the fact that there are usually two (or more) prices for a commodity unit of specific quality in any market at a given time is dulled by the convention of treating wholesale and retail prices as though they were registered in separate markets. But of course they are in fact two separate prices within the same market, differing because of a service that (at least presumptively) goes with the commodity when it is sold at retail.

When, as in the case of houses, for example, the circumstances of trade do not favor distinction between wholesale and retail prices, there remain price differences according to the conditions of sale. Even under stable and well-known market conditions the man who chooses to sell without much search for someone who particularly wants a house like his, takes one price, and the man who chooses to buy without much "shopping" pays a higher price. The difference between the two prices need not represent any exploitation of bargaining weakness, but only a fair margin for an intermediary. Or in a country grain market, a merchant may buy wheat of a farmer at one price and sell it almost immediately to a poultry raiser at a higher price. The difference, again, is likely to represent only a return for service, small in this case because a poultry raiser who had reason to believe that the difference would be large would seek out the farmer and buy from him directly.

In terminal commodity markets (and in security markets) there ap-

[41] One might choose to regard potential speculative profits foregone as a cost of hedging; but though a potential hedger may wisely take account of potential profits from speculation in deciding whether to hedge or not, I think that treating foregone speculative profits as a cost of hedging would not be the best way of taking them into account.

[42] And if the hedger maintains an exchange membership for the sake of the consequent saving in commissions, there are membership expenses to be counted as part of the cost.

[43] Using "bivalent" to mean "two-valued" rather than, as in chemistry, "having a value of two."

pear the same sort of price differences, though smaller, that provide the margin on which merchants in such markets principally operate. In large central markets the small price differences which provide these margins cannot be realistically treated as differences between a wholesale and a retail price. They tend then to be clearly reflected in price quotations only through differences between "bid" and "asked" prices.

A merchant who hedges usually finds his situation in the futures market the opposite of that which he enjoys in the spot market. In his spot dealings he buys at bid prices and sells at the higher asked prices (a fact that we ruled out of consideration in our illustrations of hedging, because we were there concerned with storage and its returns). In his futures dealings, on the contrary, he tends to buy at asked prices and to sell at the lower bid prices. At least he prefers to do so, unless the margin between bid and asked prices is so wide that he is forced to "shop" in the futures market, as well as in the spot market. The merchant is paid for his services to processors and exporters by *receiving* an asked price, and he in turn is willing to pay for corresponding services of dealers in futures by buying often of them at asked prices.

The dealers in futures from whom a hedger often[44] buys at asked prices, or to whom he sells at the lower bid prices, are the so-called scalpers, or other day traders.[45] We saw in the last section some evidence on the very narrow margin which such dealers in futures take. From that evidence it would appear that their margin is of the order of 1/14 to 1/40 of one per cent. Those figures, however, represent averages that are somewhat "watered down" by the effects of transactions between day traders themselves.[46]

Another way of estimating the dealer's margin that a hedger tends to pay on his futures transactions is from the profit margin that scalpers try for. In wheat on the Chicago Board of Trade, this has been typically 1/8 cent per bushel, or a little over 1/20 of one per cent at recent prices. An estimate so derived, however, tends slightly to overstate the margin

[44] "Often," because the purchase or sale of futures made by a hedger does not necessarily go through the hands of an intermediary scalper.

[45] A scalper, in the strict sense, may be characterized as always willing to either buy at 1/8 cent below the last price or to sell at 1/8 cent above the last price (or at such other difference from the last price as market conditions permit); he operates purely on the difference between bid and asked prices, as ordinarily understood. Other professional day traders perform an essentially similar function, but at least partially with respect to somewhat larger price differences. Bid and asked prices tend to be farther apart for large quantities than for small quantities of a commodity.

[46] The first of any pair of transactions by a scalper is made in the belief that he is buying "below the market" from an urgent seller, or selling "above the market" to an urgent buyer. But scalpers often find that they have misjudged the market, or that it has turned against them immediately after such an initial transaction. Then they seek to make the offsetting transaction quickly, often at a loss, and often to another day trader.

actually paid by a hedger, because hedgers benefit from scalpers' mistakes of judgment.

A third basis for estimating the margin that hedgers pay on their futures transactions is afforded by data showing that a loss of 0.21 cents per bushel was taken by processors and terminal grain merchants on 109 million bushels of wheat futures bought (and sold) over a nine-year period.[47] If the futures transactions were virtually all hedging transactions, as may reasonably be assumed, this indicates a hedging cost, in addition to commissions, of slightly over 1/5 cent per bushel, or less than 1/5 of one per cent of the average wheat price over the period. This is a cost figure, however, that includes speculative profits foregone[48] (or, to put the same thing in another light, that includes any return to speculators for carrying the hedges). And it is in any case a cost per bushel bought and sold, whereas the foregoing estimates of scalpers' margins might tend to be paid on purchases and on sales alike. So there is at least no evident inconsistency between these data and the previous estimates of scalpers' margins.

Whether scalpers' margins are less than 1/10 per cent, or as much as 1/5 per cent, a merchant or processor can afford that cost in addition to

[47] The data, from Blair Stewart, *An Analysis of Speculative Trading in Grain Futures,* U. S. Dept. Agric., Tech. Bull. No. 1001 (Oct. 1949), Table 27 (the calculations of loss per bushel are mine) are as follows:

Business	No. of Firms	Transactions (thousand bushels)	Loss (thousand dollars)	Loss per Bushel (cents)
Terminal grain merchants	45	76,054	174	0.23
Processor	44	33,407	55	0.17
Total	89	109,461	229	0.21

Similar data, from the same source, on hedging transactions amounting to 9.6 million bushels by 33 country and subterminal grain merchants, show a loss of 2.6 cents per bushel on their transactions in futures. The magnitude of this loss indicates that more of the hedges against wheat stocks by this group of dealers were carried in periods of rising prices than in periods of declining prices. The classes of grain merchants involved commonly practice discretionary hedging, and those represented in the data apparently chose to hedge at such times that they "protected" themselves against profits from price increase somewhat more than against losses from price decreases. The results tabulated above for terminal grain merchants and processors may also be affected to some extent by the practice of discretionary hedging, though it is much less prevalent among such wheat handlers than among country and subterminal merchants.

[48] Which we wish to leave out of account here, as previously noted. It is scarcely possible to deal with them in general terms, except in such a global average as the one just given, because their magnitude depends so much on special circumstances, including the knowledge and judgment of the hedger.

commission charges of, say, $\frac{1}{10}$ of one per cent.[49] His own dealer's or processor's margin, though small, is usually several times the total of these costs of hedging.

In small and relatively inactive futures markets, however, scalpers must take much wider margins than in the circumstances to which the foregoing data apply.[50] They must do so primarily because their volume of business is restricted to perhaps half-a-dozen transactions per day, or less, as compared with the 70 transactions per day of the cotton trader cited. And, secondly, they must do so because their risks are greater. In an active futures market, a scalper can usually buy and resell within the space of a few minutes, running little risk that some change in news will involve him in a serious loss. In inactive markets, purchase and sale may be separated by hours, or the scalper may buy today and have to wait until tomorrow to sell, running correspondingly large risks of loss from unpredictable developments. And because scalpers must take wider margins on inactive markets, hedging on them is more costly than on active futures markets.[51] Consequently, if a hedger has two futures markets to choose between he tends to do his hedging in the more active one.[52]

The element of hedging cost that arises from scalpers' margins, or from the inconvenience and price disadvantages incurred in the absence of scalpers, explains the restriction of trading almost universally to a single futures contract on one exchange, in the same way that it explains the tendency for futures trading in a commodity to concentrate mainly or wholly on some one exchange. When two futures contracts are offered for trading applying to different descriptions of the commodity, trading tends to become more active in one of them than in the other; scalpers' margins then rise on trading in the less active contract, leading to

[49] Commission charges are not fixed as a percentage of the price; expressed so, they depend on the price, and they vary rather widely among commodities and exchanges, and according to whether the transaction is for a member of the exchange or a nonmember. The figure of $\frac{1}{10}$ of one per cent is representative of commissions for commodities and exchanges with a fairly large volume of business and low commission rates, and is therefore applicable to most of the hedging that is done.

[50] Part of the difference in gross profit obtained per $100 of transactions by the two day-traders for whom data were given, is accounted for by the fact that the second trader operated mainly in commodities which have only moderately active trading.

[51] At some point not very far down on a scale of diminishing market activity, it becomes impossible to conduct scalping as a specialized form of trading and to make a living at it. Then the scalping function is performed by some speculators, and the distinction between scalping and speculation becomes blurred.

[52] The preference, as commonly expressed in trade circles, is for a "broad" market as against a "thin" market. This terminology expresses the fact that size as well as frequency of transactions is important. On the supposition that most readers would understand "active" to mean about what a trader calls "broad," I have thought it unnecessary to introduce the trade terminology into the exposition.

further concentration of hedging, and of other trading, in the more active contract. For example, after five years of use of the Californian wheat contract for futures trading at Liverpool, trading was initiated also (in 1891) in an American Red wheat contract. The latter proved the more popular, and in spite of the important difference between the two kinds of wheat, quickly drew trade away from the Californian contract to such an extent that trading in the Californian was presently abandoned.[53] Maintenance of futures trading in two descriptions of a commodity on any one exchange was found generally impractical early in the history of futures trading, and has rarely been tried in recent years.

These conclusions have some interesting implications. If we are correct in inferring, as seems necessary, that hedgers' responses to cost differentials account for the observed tendency toward concentration of futures trading dominantly or wholly in some one exchange, and wholly in some one contract on each exchange, it follows that hedgers are as a rule unwilling to pay for superior hedging facilities. Does this mean that hedging is usually considered worth while only if it is very cheap—that its advantages are really not very great? Or does it mean something else?

VI. *"Insurance" Hedging*

The question posed above may well be considered in a concrete situation. Grain merchants and flour millers in the Pacific Northwest of the United States have long sought to gain and hold the advantages of futures trading in a contract well suited to their needs. Largely because of the great distance between that area and the main wheat-producing regions of the country, wheat prices in the Pacific Northwest are only loosely tied to prices at Chicago or Kansas City. When the Chicago futures price represents hard wheat, as has commonly been the case,[54] the important quality difference between hard wheat and the soft wheat typical of the Pacific Northwest contributes to disparity of movement between Chicago and Pacific Northwest wheat prices. No. 1 Soft White wheat in Portland or Seattle may sell at 20 to 30 cents per bushel under the spot price of contract wheat at Chicago, or it may sell at 10 cents per bushel, or more, above the Chicago price. Chicago futures consequently afford a very imperfect hedge for soft wheat in the Pacific Northwest.

Efforts to provide good hedging facilities for Pacific Northwest wheat have included maintenance, over many years, of futures trading at

[53] *Cf.* Holbrook Working and Sidney Hoos, *op. cit.*, p. 144.

[54] Though during the last few years the Chicago future has most of the time been effectively a soft-winter wheat future because the deliverable soft wheat was cheaper than deliverable hard wheat.

Seattle and, until 1942, at Portland also. These markets did not flourish,[55] and in 1950 the experiment was tried of providing for trading in North Pacific Coast wheat futures on the Chicago Board of Trade (with delivery on the Pacific Coast). The special Chicago contract failed to attract enough business to warrant its continued use; it seemed to serve only to draw business away from Seattle.

The volume of hedging in a Pacific Northwest wheat futures contract must necessarily be a fairly small fraction of total wheat hedging in the United States, because total wheat production in the area is only some 10 to 12 per cent of the national wheat crop.[56] Moreover, there is relatively less occasion for hedging in the Pacific Northwest than in most other areas of concentrated wheat production in the United States, because of abundant "country" storage facilities and a widespread disposition of growers to retain ownership of their wheat for considerable periods after delivery.[57] But even so, there could have been a lively business in Pacific Northwest wheat futures if commercial stocks of wheat in that area had not been held to such a large extent either unhedged, or hedged in futures markets of the Middle West, especially Chicago (and in the standard contract there).

Decision of a wheat merchant or processor in the Pacific Northwest to hedge in Chicago futures rather than in a Pacific Northwest futures contract is only a rather extreme example of the sort of decision often made by hedgers—to take inferior risk protection for the sake of a saving in cost. Even though he hedges in Chicago futures, a merchant or processor in the Pacific Northwest can still rely on prices of the Seattle futures for guidance in deciding whether to buy for storage or not to buy.[58] If he buys because the relation between the spot price and a Seattle futures price promises a return for storage, he may still decide to hedge in a Chicago future with only the result that he will take more risk, but not so much risk as though he held the wheat unhedged. In other words, the decision on where to place the hedge concerns only the insurance aspect of hedging.[59]

[55] See data on open contracts in wheat futures, by exchanges, in *Commodity Futures Statistics*, U. S. Dept. Agric., Stat. Bull. No. 107 (1952), pp. 5, 10, and earlier publications in the series.

[56] Opinions differ as to how the "Pacific Northwest" wheat area should be defined, but on any reasonable definition, it does not follow the boundaries of states, which are the units for wheat production statistics; consequently the production of the area can be stated only roughly.

[57] *Cf.* J. S. Davis, "Pacific Northwest Wheat Problems and the Export Subsidy," *Wheat Studies* (Aug. 1934), X, 377.

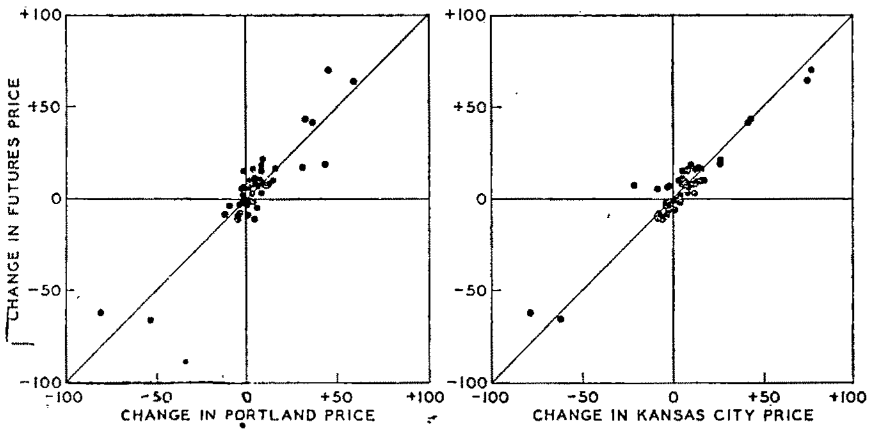
[58] Though of course, if too little hedging is left for the Seattle market, even the guidance afforded by its prices will be lost.

[59] Unless he expects a change in the relation between Seattle and Chicago prices, in which case the hedging problem becomes entangled with one of intermarket arbitrage.

A merchant or processor choosing between Seattle and Chicago futures as the medium for hedging that he has decided to do is in much the same position as though he were taking out casualty insurance, and choosing whether to take full coverage or coverage only for losses above some stated minimum. The choice he makes is whether to take coverage on all insurable risks, at a fairly high cost, or to insure only against serious loss, at a considerably lower cost. The chief function of insurance is to give protection against serious, crippling, loss. Carrying insurance against small losses that occur frequently is ordinarily poor business because the holders of the insurance have to pay the losses,

CHART 1.—RELATIONS OF TWO-MONTH CHANGES IN PRICES OF CHICAGO WHEAT FUTURES TO SIMULTANEOUS CHANGES IN PORTLAND AND KANSAS CITY SPOT PRICES, SEPTEMBER 1946 TO MAY 1952*

(*cents per bushel*)



* Data as for Table I; in each crop year the first change calculated is for July–September (September–November in 1946, when futures trading was temporarily discontinued until late August on account of price controls), and the last price change, for March–May.

through the insurance premiums, and to pay also the overhead costs of writing policies and adjusting losses. Hedging, as we saw earlier, is not ordinarily done primarily for its insurance value, but because it is a logical consequence of the information on which the hedger acts (p. 325). The fact that business risks attending such hedging are very small is none the less a valued consequence of such hedging; and when the costs of hedging in the futures contract logically indicated are excessive, businessmen naturally consider the possibilities of obtaining at least the insurance values of hedging at a moderate cost. The principal insurance value of hedging wheat stocks in the Pacific Northwest is supplied about as well by Chicago futures as by Seattle futures.

This interpretation of hedging deserves empirical support. Is a

[c] Spot prices of No. 1 Soft White wheat, compiled by U. S. Department of Agriculture.

"poor" hedge reasonably comparable with insurance that covers losses above some stated minimum? Or is it more properly comparable with insurance covering only a *fraction* of the total loss; or with insurance carried with a company of uncertain financial status, that may turn out to be no insurance at all? The facts are well illustrated by Chart 1.

The meaning of the points plotted in the chart may be grasped readily by considering their relation to the illustrative data in Table I. The point, for example, that appears at the extreme lower left of each section of the chart, is plotted from the data for "two-month price changes" appearing in the table opposite "Feb. 14." These are price changes from December 16, 1947 to February 14, 1948. Over this two-month interval, the spot price at Portland fell 81 cents; that at Kansas City fell 79 cents; and the price of the Chicago May future fell 62 cents. Despite these severe price declines holders of wheat stocks of the indicated qualities at Portland and Kansas City, hedged in the Chicago future, would have lost only 19 and 17 cents per bushel, respectively.

Points on the diagonal line across the center of each section of the chart represents instances in which the spot and the futures prices

changed equally. Points to the left of this line represent instances in which the spot price fell more than the future price, or rose less. These were instances in which hedged stocks would have been carried at a loss, as in the specific case just considered. Conversely, points to the right of the diagonal represent instances in which a gain would have resulted from the carrying of hedged stocks. Nothing further need be said here about the way in which hedgers use futures quotations to judge in advance when the carrying of stocks is likely to prove profitable, but it is pertinent to note that Table I includes evidence that a hedger anywhere in the Middle West, at least, had reason to expect a loss if he carried stocks of wheat from December 16, 1947, to February 14, 1948. This prospect was indicated by the fact that on December 16 the price of the Chicago May future was 13 cents under the price of the December future.[60]

Amounts of gain or loss from carrying hedged stocks of wheat are indicated directly in Chart 1 by the horizontal (or vertical) distances of the plotted points from the diagonal line. The scatter of the points is greater, and therefore gains and losses were greater, for Portland wheat than for Kansas City wheat, though perhaps not so much greater as some would have expected. But the important fact for present purposes is that the points in the chart cluster as closely around (or are no more widely dispersed around) the diagonal lines near their ends than near their midpoints. There is no evident tendency for gains and losses on hedged stocks to have been larger when price changes were large than when price changes were small. Hedgers take some risks even though they can estimate fairly well the prospective gain or loss from storage, and a good deal more risk on wheat stored in Portland and hedged in Chicago than on wheat stored in Kansas City and hedged in Chicago. But in either case the amount of risk is substantially *independent* of the amount of price change. Hedging limits the amount of risk in substantially the same sense that insurance covering losses above a stated amount limits risk.

In the light of these facts, it is understandable that many hedgers should prefer a "poor" hedge that is cheap to a more nearly perfect hedge that is relatively expensive. The tendency for most futures trading in any commodity to converge in some one exchange, and to concentrate in some one contract there, is explained. There is even an implied suggestion that trading in barley futures, for example, may have died out in the United States because grain dealers chose commonly to

[60] This relation reflected a current high premium on spot wheat over the May future, indicative of prospective declines in spot prices relative to the May future throughout the United States east of the Rocky Mountains, but not necessarily on the Pacific Coast.

hedge their barley stocks in corn futures, at low cost, in preference to hedging in the small and relatively inactive barley futures market, where the costs of hedging were relatively high. And the fact that merchants and processors make such choices does not necessarily indicate that they put a low estimate on the value of hedging. Their valuation of hedging must be judged from cases where the only choice open is to hedge in a market where hedging is expensive, or not to hedge at all. In such cases the common choice is to hedge, as is evidenced by the vitality of small futures markets that have no larger competitor.

VII. *Summary*

To summarize, we began with a definition of futures trading that related it intimately to other commodity transactions, and emphasized economy as its major distinguishing feature. A language problem, we found, has promoted a false idea of contrast between futures trading and other commodity trading. Looking at the bases of futures trading, we saw them to lie more in utilization of the advantages of futures markets by merchants and processors, for hedging, than in the desires of others to speculate.

Hedging we found to be not primarily a sort of insurance, nor usually undertaken in the expectation that spot and futures prices would rise or fall equally. It is a form of arbitrage, undertaken most commonly in expectation of a favorable change in the relation between spot and futures prices. The fact that risks are less with hedging than without is often a secondary consideration. The prevalent tendency to regard curtailment of business risks as the main service of futures markets has diverted attention from their probably more important service of promoting economically desirable adjustment of commodity stocks, thereby reducing price fluctuations. The argument for governmental stockpiling rests heavily on a consequent false appraisal of the causes of price fluctuations.

In further consideration of the subject of price fluctuations, we stated an ideal of behavior of a futures price that permits objective statistical tests, and put in one sentence the gist of conclusions arising from application of such tests to the intraday behavior of futures prices. The statement of conclusions was prefaced by some data on the operations of two professional traders which reveal characteristics far from those usually imagined to exist. Pending further research based on the stated concept of ideal price behavior, inferences on the reasonableness of the larger fluctuations of futures prices, beyond the limits of one trading session, must still rest largely on subjective judgment, but there is considerable evidence that these larger price fluctuations may usually re-

flect substantially accurate appraisals of changing economic facts that should be accompanied by such price changes.

Finally, we inquired into the causes of some puzzling characteristics of futures trading and found them explained by hedgers' responses to cost differentials associated with the "bivalence" of market price. The responses themselves depend largely on the fact that even a "poor" hedge affords good protection of the sort for which insurance is mainly needed. It is like casualty insurance covering losses above some stated minimum.

ECONOMICS OF HIGHER EDUCATION

By SEYMOUR E. HARRIS*

The Commission on Financing Higher Education (hereafter referred to as the Commission) recently released its Report, *Financing Higher Education in the United States* (hereafter referred to as *Report*) and ten research volumes, inclusive of a 500-page Staff Report (hereafter referred to as *Millett*), by John D. Millett, executive director. The Commission consisted of twelve members: college administrators (8), and businessmen and lawyers (4). The executive committee consisted of Messrs. P. H. Buck, F. A. Middlebush, and H. M. Wriston. No economist was included, though the problems were primarily economic, and no nonadministrative faculty member was included.

This Commission has written an important report, for which all should be grateful; and it has made available an abundance of materials which will greatly lighten the tasks of researchers in this field for many years. Both the Rockefeller Foundation and the Carnegie Foundation are to be congratulated for their generous donations for the work of this Commission, which made possible the provision of so much valuable material.

These eleven volumes offer an opportunity to discuss the vital economic issues confronting Institutions of Higher Learning (hereafter referred to as IHL). At the outset, however, we should note some peculiarities of the market for college students. First, many potential "buyers" are excluded from the market. Students have to meet minimum standards (*e.g.*, a high school diploma). Such restrictions limit the number of "buyers" of higher education. Second, buyers are not usually asked to pay the full costs of an education. The effect of "sales" below cost is to increase numbers seeking a college education, though the net effect here is not so great as is commonly supposed (except in medical schools, where a tuition of about $700 per year is to be set against a cost per year of about four times the tuition). For private institutions, the "subsidies" per year amount to about $120 and for public institutions about $260, or an average of almost $200. These sums are large in relation to *educational* costs (one-third of educational costs for private institutions, two-thirds for public), but much less relative to the $1,000 to $2,000 total cost in private IHL and a minimum of $1,000 for in-students at state IHL, plus in each instance the income foregone. Costs for nonresidents are less.[1] Education below cost is offered despite the fact that a college graduate can look forward to an income of $100,000 more than a noncollege graduate and a medical school graduate, $300,000 to $400,000 more.[2]

* The author is professor of economics at Harvard University.

[1] Figures calculated from *Millett,* pp. 140, 300-01, 389.

[2] *Cf.* E. Havemann and P. S. West, *They Went to College* (New York, 1952), p. 26, and my article "Why the Government Need not Subsidize Medical Schools," in *The Reporter,* Feb. 5, 1952, VI, 24.

Third, the competition is not primarily a price competition but rather one for attracting the most-qualified buyers, that is, the highest quality students. Fourth, the major costs of education, inclusive of extra costs of living and income foregone, are still borne by the individual, though there is a strong public interest involved.

I. *Symptoms of Financial Distress*

It is generally assumed that IHL are in financial difficulties. The Commission also makes this assumption, and lists as factors accounting for the financial problem: inflation, expansion of services, fluctuating student enrollments, needs for enlarged and modernized plant, and uncertain sources of income from gifts, endowment, and government (*Report*, p. 59). We shall return to these factors.

But actually are IHL in distress? Some statistics do not confirm this. Surely, enrollment does not suggest that IHL are in trouble. Fall enrollment in various years was as follows:

Year	*Enrollment*	*Index* (1939 = 100)
1939	1,364,815	100
1943	733,190 (minimum)	54
1949	2,456,841	180
1951	2,116,440	155

Source: *Millett*, p. 67.

It is not generally held that financial difficulties spring from an increased number of customers. (The decline of 14 per cent from 1949 to 1951 is explained by the reduction in "back-log orders.") The Commission is not too helpful in clarifying the relation between enrollment and financial position. Indeed, they point to the fact that "one-third to two-fifths of expenditures may be required for overhead, student personal services, the library, operation of the plant and other activities" (*Report*, p. 80). As the number of students rises, the apportionment of fixed costs over a larger number should bring about a reduction in costs per student; and on top of a 30 per cent rise of enrollment in the 'thirties, the average enrollment in the years 1946-51 exceeded that of 1939 by two-thirds (calculated from *Millett*, p. 67). In fact, Millett shows that, with rising enrollment, costs increase by but 50 per cent of the additional student charges received, and with declines the IHL profit from a reduction of costs of but 50 per cent of student charges foregone.[3] Moreover, it is shown that average expenditures for administration and general purposes were $183 for liberal colleges with enrollment of 500 or less and $118 for those with enrollment of 2,000 or more (the relation of size and costs is an inverse one throughout). "As a general proposition it seems fairly evident that large enrollments are economical as far as expenditures per student are concerned" (*Millett*, p. 175). Moreover, the large rise of enrollment is mainly concentrated on a relatively unchanged number of institutions. Should we leave the junior college out, the increase in numbers of IHL from 1940 to 1950 was but 4 per cent, and with junior colleges included, 12 per cent (*Millett*, p. 103).

[3] Undoubtedly, this oversimplifies the problem. *Cf. Millett*, p. 272.

Hence I conclude that, however difficult planning becomes with uncertain enrollment, the Commission has not proved its point that fluctuations in enrollment account for financial difficulties—unless IHL unwisely expanded capacity irretrievably in response to the veterans' bulge, which generally was assumed to be temporary. (There was some evidence of great pressures felt by *liberal* colleges to increase commitments in response to higher enrollment in the early postwar period.) Perhaps a more accurate way to put this point is that IHL would fare better with stabilized (or better, steadily rising) enrollment, but any financial problems raised by past fluctuations in enrollment have been *more* than offset by the rise in enrollment, accompanied by a reduction in costs per student, the result of economies of scale.

Before leaving this point, I should add the following, lest my position be misunderstood: First, I am not discussing now the problem of inflation, which, of course, raises costs per student in dollars. Second, it is possible that a rise of enrollment of, say, 50 per cent raises problems of new plant and personnel which may put an increased burden on IHL. (I am reminded of the rise of traffic on the railroad which requires a new track.) In the postwar years, however, the construction of new plant was only to a small extent based on expectations of continued enrollments at the peak 1948 level. Third, as student enrollment rises, the contribution of past accumulations of capital or even of current gifts, declines per student. This means that greater recourse has to be had to student fees or public aid. But it also means that for every rise in enrollment, the contribution of additional student income increases relative to costs.

The conclusion is that in the postwar years IHL gained from the rise of enrollment in that costs per student did not rise as much as revenue per student. Where, however, student revenues are small in relation to additional costs per student (*e.g.*, medicine), large losses result from increased enrollment.

What then is the evidence of financial difficulties for IHL? Clearly the rise of enrollment should not raise serious problems, for it is clear that with that rise marginal revenue exceeded marginal costs. Nor do the income statements of IHL suggest serious problems as of today. Thus, in 1950 income was estimated at $2,182 million and expenditures at $2,069 million. The excess of receipts on current account was greater than in 1940 or 1930, though not on a percentage basis. One may ask why, in view of these summary figures, there is so much public discussion of the colleges being in the red. The answer seems to be partly that many private IHL include as receipts only student payments and returns on endowment, with the result that substantial deficits are shown. Gifts, of course, make up the difference. "For fund-raising purposes some college administrators prefer to show the 'deficit' as an encouragement to their campaign for gifts" (*Millett*, pp. 282-83). So far the evidence of distress is unsupportable. But we shall show that IHL face serious problems nevertheless.

Inflation is one of the important causes of financial difficulties. Rising prices hurt, because receipts often do not respond to the rise of costs. According to a crude price index, constructed with the aid of Professor George Stigler, the prices paid by IHL had risen by 7•.2 per cent in 1950 vis-à-vis 1940 (*Millett*, p. 116). (This is about 4 percentage points more than the rise in the consumers price index.)

In response to inflation, student fees have not risen *pari passu*. On the basis of figures for enrollment and tuition fees given by Millett, I estimate the rise of tuition by 1950 at 50 per cent, or about two-thirds the rise of prices. Here is a loss to be associated with inflation; for fees are the most important single source of revenue for private institutions, and the second most important for public IHL (*Millett*, p. 297).

This is not, however, a full statement of the situation created by inflation. The Commission devotes much space to the inflation of costs; but in all fairness they should have concentrated equally on the rise of income of the nation. To some extent the rise of income reflects the inflationary process, both the rise of prices and the effects of that rise on output; and to some extent higher income reflects the increase of output associated with gains of employment and productivity not related to inflation. *Nevertheless, the fact is that if inflation is a handicap, the rise of money income is a boon.*

This rise of income largely explains the increase of budgets of IHL from $624 million in 1940 to $2,068 million in 1950 (*Millett*, p. 280). This rise, it should be noted, even exceeded that in national income. Against an increase of prices of 75 per cent, IHL increased their revenue by 230 per cent. Though fees per student rose by substantially less than costs, the rise of enrollment and other income associated in part with the gains of national income made possible the vast income gains of IHL. To present a full picture we should consider both inflation (a cost factor) and rising national income (a receipts factor).

Is there, then, any evidence of financial distress, or at least of inadequate resources? One symptom is the larger part played by tuition in total costs. In private universities, tuition accounted for 46.7 per cent of all educational income; in private liberal arts colleges, 71.7 per cent; in private professional schools, 46.1 per cent. From 1940 to 1950, student fees in private IHL rose from 57.7 per cent of all educational income (adjusted) to 67.8 per cent; and in public IHL, from 22.5 to 29.8 per cent (*Millett*, pp. 292, 300-01).

It is unfortunate that student fees constitute a rising percentage of income; first because, as the Commission observes, this makes IHL too dependent on a source of revenue that varies with enrollment. The effects on competition for students in debasing of standards is obvious. Second because the increase in fees is an antidemocratic element in higher education. (We shall return to this problem later, when we discuss enrollment and alternative methods of solving financial problems.)

Before we leave this aspect of the problem of tuition, we should emphasize one point. The gains of students from a reduced tuition fee in *real* terms over the period of 1940-50 should be contrasted with the increased *real* tuition fee from 1930 to 1940. A comparison of 1930 and 1950 might in many ways be a more appropriate one than that of 1940 to 1950. In fact, from 1913 to postwar, there is much evidence of a substantial rise in the "real" cost of higher education.[4]

A second symptom of financial distress, or at least of inadequate resources,

[4] *Cf.* my *How Shall We Pay for Education* (New York, 1948), pp. 173-81.

is the pay of faculty members. A college is no better than its faculty. Badgered by higher costs for supplies, construction, nonfaculty salaries, etc., the IHL respond by squeezing its faculty. In general, the result is bound to be felt in the quality of men and women drawn into teaching, a result that is furthered also by the increase in work load.[5]

The Commission shows that salaries in IHL have risen much less than in other occupations. Whereas, on the basis of a substantial sample, average academic salaries in public universities were 2.21 times full-time earnings of all employees for the country in 1940, they were but 1.43 times in 1950. This is aside from the gains resulting from reduced unemployment in industry (*Millett*, pp. 274-75). Actually, except in land-grant colleges, pay rose substantially less than the cost of living (50-60 per cent against a rise in the cost of living of 72 per cent).[6] The rise of pay has been small compared to that of other professional groups. This rise of 50-60 per cent should be compared with one of about 150 per cent for physicians, 100 per cent for dentists, of almost 100 per cent for lawyers.[7] Again, we make one reservation: that the reduced economic status of faculty members is greater if comparison is made with 1940 than with 1930.[8]

Should faculty salaries be raised by 25 per cent, the gain over prewar would roughly be 100 per cent; and the average increase would approach that of other professions except for medicine. For the $708 million of departmental instructional outlays in 1950, this would involve an additional outlay of close to $200 million, or more than $1,000 per faculty member (there were 155,000 faculty members in 1947). The $200 million figure also allows for higher salaries in library, extension, and research. This increase of 25 per cent would seem to be a minimum as a condition for fair competition with the other professions and business. It makes no allowance, of course, for any later doses of inflation.[9] I might add that, in 1948, I estimated that an increase of faculty salaries in *private* institutions which would put them in the same relative position as other members of the labor market would require $200 to $225 million additional per year. At that time, faculty salaries *relative* to income in the economy had been reduced by 40 per cent in real terms.[10]

[5] See, for example, *Higher Education for American Democracy: Report of the President's Commission on Higher Education*, hereafter referred to as *PC* (Washington, 1947), IV, pp. 51-52. Here it is noted that teaching burdens are heavier than before the war.

[6] *Millett*, pp. 131-36; *cf.* also S. E. Harris, "Professional Salaries and Tuition, 1947-48," *Bull. Am. Assoc. Univ. Professors*, Spring, 1948, XXXIV, 98-109.

[7] *President's Commission on Financing of Health Services*, Preliminary, Table D-33, (Washington, 1952).

[8] It should be observed that all estimates of average salaries are subject to one important reservation: the proportion of members of different grades or age group varies. Thus, in 1950, there was a much larger proportion of young members and hence the rise was more than it seemed to be; but the percentage rise varied inversely with rank.

[9] For budgetary figures and number of faculty personnel, see *Millett*, p. 118, and *PC*, VI, pp. 38-40.

[10] "The Future of Higher Education in the United States," *Harvard Educational Rev.*, Fall, 1948, XVIII, 202.

Still another indication of financial difficulties is given by an examination of outlays per student:

EXPENDITURES PER RESIDENT STUDENT, 1930, 1940, 1950

	1930	1940	1950
Instructional Expenditures—in Current Dollars			
All Institutions	$217	$189	$300
Educational and General Purposes—in 1940 Dollars			
All Institutions	289	291	277
Universities	291	319	292
Liberal Arts Colleges	284	292	253
Professional Schools	299	277	281
Junior Colleges	230	171	240

Source: *Millett*, pp. 116–140.

In dollars of stable purchasing power, the outlays per student have tended to decline since 1930 and especially since 1940. The reductions are especially large since 1940 for liberal arts colleges. These figures in themselves do not necessarily mean a debasement of standards, for account must be taken of (1) the economies of scale associated with the rise of enrollment and (2) the exploitation of faculty members. Yet it is significant that in a period when real per capita income (even after taxes) had risen by almost 55 per cent, the real outlays per student actually declined. That the number of resident students from 1940 to 1950 per full-time faculty member rose from 11 to 12 and for liberal arts colleges, from 13 to 15, points to less effective teaching (*Millett*, p. 130). The status of the physical plant, to which we now turn, is also relevant.

PLANT OF IHL, VALUE AND COST OF OPERATION, 1930, 1940, 1950

	Plant Value ($ million)			Plant Operation and Maintenance ($ million)	Plant Operation and Maintenance per Resident Student ($)
	All Plant ($ million)	Public[a]	Private[a]		
1930	2,053	882	1,056	57	58
1940	2,754			63	47
1950	4,800	2,642	1,848	201	85

[a] Included here are only universities, liberal arts colleges, professional schools, and teachers colleges.

Source: Calculated and compiled from *Millett*, pp. 165-66, 256-57, and *Report*, pp. 86-87.

The reader will observe that from 1930 to 1950 the rise of plant value has

been more than twice as great for public institutions as for private; that costs of plant operation and maintenance have risen by 2½ times as against a rise of ½ times in cost of operation per resident student and a rise in total value of less than 1½ times.

All conclusions drawn from these figures are subject to serious reservations; for there is little indication of how plant is carried on the books: original cost? replacement value? (The *PC* estimated replacement value at $4 billion in 1947.)[11] Nevertheless, we note that maintenance and operation expenses have risen about three times as much as the cost of consumer goods. The explanation lies partly in the large rise in the costs of the relevant types of labor; in the increase of plant; in the deferred maintenance associated with the war.

The general view seems to be that plant is too old and inadequate for the job to be done. The U. S. Office of Education has estimated construction needs until 1960 at $5 billion; the *PC*, at $8.3 billion (assumption of 4½ million enrollment and re-establishment of prewar space per student); the Commission, $3.6 billion (assumption of 2½ million enrollment and 1948-1949 prices; at present prices, the amount would be in excess of $4 billion).[12]

Even if the needs are put only at $4 billion, it may be concluded that the financial burden would be great. The sum involved seems to be equal to the replacement cost of existing plant; and the outlays per year about 20 per cent of all expenditures for higher education per year. They may well point to serious financial problems for IHL.

Undoubtedly, the financial problems of IHL are serious; and that despite the fact that the Commission has allowed inadequately for the effects of rising incomes. In particular, the reduction of the significance of endowment income and gift income generally (more on this later), the failure of instructional incomes to rise sufficiently to match incomes of competing employments, the failure of real outlays per student to keep up with the gains of the economy, the unfilled needs for construction, the threat to enrollment associated with security—all these point to financial embarrassment, or at least serious problems.

The crucial problem is how can expenses be cut or income increased. On the former, the Commission makes a notable contribution. All kinds of possible economies are suggested and wastes pinpointed (especially *Millett*, pp. 123-30, 167-72; *Report*, 96-99, 105-13).

II. *How to Increase Income*

The major suggestions of the Commission are to obtain more money from business, especially from corporations, and from state governments. It is not easy to pierce this problem because the figures are presented in such a way that the contribution of each source of income is not clear. *Millett* (p. 292) gives a breakdown, not for all institutions, but for each of four groups. From *PC* and Chapters 15 to 19 of *Millett*, I piece together the following:

[11] *PC*, V, p. 18.

[12] *Millett*, pp. 259-63; *PC*, V, pp. 20-21.

PERCENTAGE OF EDUCATIONAL AND GENERAL INCOME FROM SOURCES INDICATED, ALL INSTITUTIONS' COMMISSION ESTIMATE, 1950; *PC* ESTIMATE, 1960*

	Commission Study[a]	*PC* Estimate[b]
Student Fees	29.8	17.3
Endowment	13.9	8.7
Benefactions	6.2	
Federal Government	27.9 (12)[c]	33.0
State and Local Government	55.2 (38)[c]	39.6
	131.0	98.6

[a] Expenses, $1,677 million.
[b] Percentages estimated on basis of 4.6 million enrollment for 1960. Estimated expenses (operating only), $2,587 million.
[c] Corrected figure.
* Source: *Millett,* p. 292 and Chs. 15-19; *PC,* V, pp. 42, 48.

Even if the Federal Government percentage is corrected to allow for the fact that outlays by the Veterans Administration are included in Student Fees, the Commission figure still adds up to 115 per cent. Probably the difference between 115 and 100 per cent is accounted for by the exaggerated allocation to state and local expenditures. (Part of these outlays are not available for educational purposes.) I have therefore put in brackets corrected figures.

As we shall see later, the *PC* estimates understate the contribution of government; for excluded here are proposals for scholarships and capital outlays. Federal outlays then rise to 47 per cent of the $4.3 billion encompassed, and the percentage contributed by the others declines.

A. Student Fees

Let us consider each of the sources of revenues in turn. Although its position is not stated too clearly, the Commission seems opposed to large increases in tuition fees. One reason seems to be that the private institutions are confronted with the competition of public institutions. A second, the unwisdom of depending too much upon an unstable form of income, unstable because of the dependence on enrollment. A third reason is the democratic argument: education must not be made too expensive for the deserving but poor students. The Commission, on the other hand, does point to the much larger proportion of families that now come within the income group able to pay the costs of higher education (*Report,* pp. 133-34).

I wish that the Commission had been bolder in its recommendations. Do not charge according to the cost of the program. Correct. But why not charge according to the gains to be obtained from higher education? That is, on the assumption that these gains are reflected in the later income of the college graduate, why not require that each college graduate and professional school graduate pay a share of the full cost of higher education that will be proportional to his ability to pay in college years and after? In the years of education the poor student would presumably pay nothing, the wealthy student would

pay the full educational costs over four years (say, $1,600), or even somewhat more (see below), and the average student perhaps $800. According to economic conditions and as the IHL gradually accumulate funds from graduates who pay the difference between costs and undergraduate payments while at IHL, the proportion of the $1,600 paid in college years could be reduced. After graduation, each former student would continue to make payments over the earning years, but the size of the individual's payment would be a percentage of his income—the average percentage being so determined that the total sum thus collected from all graduates over a number of years would suffice to pay the total cost of their education, less what they paid as undergraduates and less any scholarship aid made available to the impecunious and able. Each graduate would pay the same percentage with the reservation that there would be a ceiling on the total amount paid. A wealthy alumnus would then be required to pay more than cost, but the excess would be an insurance premium to offset losses resulting from premature deaths, low incomes of some graduates and defaults on the part of others. A student who paid nothing during his college years would of course be required to pay a larger percentage than the student who paid a large part of costs inclusive of the insurance premium during his college years. Thus the individual with an average income during and after college might pay the full cost of his education, those with incomes above the average would pay more, and those with small incomes during college and after would pay little. I should like to see this proposal applied to both public and private institutions, with the result that pressures of state legislators and unfair competition of public institutions would be reduced.

Medical school graduates would be required to pay about $12,000 plus $1,600 for the A.B. (Perhaps $3,000 would be paid during educational years.) Thus, the sum involved in posteducational payments would be about 2 per cent of the lifetime income (about $500,000) of the average physician. Incidentally, the federal government in taxes remitted might well pay one-third of this cost, as the payment may be classified as a gift. (The obligation would be a moral one, and the rate might be increased slightly to cover deaths, failures to pay, etc.)

But let us consider the difference in approach of the *PC* on the one hand and the Commission on the other. It will be recalled from the preceding table that 30 per cent of all income came from student fees in 1950. The contrast in approaches is suggested by an examination of the 1950 distribution of income and proposed income for 1960 under the plans of *PC*, with anticipated enrollment of 4.6 millions. Despite a doubling of enrollment, *PC* calls for students contributing but 17 per cent of the $2.6 billion involved, whereas the actual contributions in 1950 were 30 per cent of $1,677 million. Since the Commission is seeking to raise income by a few hundred million dollars and is concentrating its attention primarily on business and state government as sources of new revenue, the conclusion may be drawn that the proportion to be provided by tuition under the Commission's proposals might fall a little but not rise.

The contribution of tuition depends in part upon the enrollment and in part

upon policy issues. Here, then, is a striking contrast between the Commission and *PC*. Whereas the Commission is inclined to restrict higher education to a limited number, on the grounds that those should have it who can profit by it, *PC* is much more disposed to open the gates wide. Whereas the Commission seems to put the appropriate number at 25 per cent of the college age population, *PC* would welcome 49 per cent through the fourteenth year (sophomore year or junior college) and 32 per cent through advanced liberal or specialized professional years.[13]

The difference in approach toward enrollment is also reflected in student charges. *PC* emphasizes economic disabilities as the explanation of loss of talent and limitation on numbers. Hence the small dependence on tuition. The Commission, basing itself on a valuable study made for it by B. S. Hollinshead *(Who Should Go to College)*, draws attention to noneconomic motivation. Of the top 25 per cent on the basis of intelligence tests who might go to IHL, only 40 per cent actually do, and of these 40 per cent only one-half graduate. In other words, but one-fifth of those who should profit from a college education actually attain it (*Report*, p. 49).

B. Government Contributions

Perhaps the main contrast in approach between these two reports is that which appears in their attitude towards contributions from the federal government. It will be noted that, in 1950, contributions of the federal government (exclusive of Veterans Administration) accounted for 12 per cent of the total income of IHL, and that *PC* plans called for 33 per cent. In fact, the total amount was presently to be $850 million (the counterpart of the 33 per cent) and substantial additional amounts for construction, scholarships, and fellowships. *PC* would have the federal government contribute money for scholarships, fellowships, operating expenses, and research. In contrast, the Commission is against any extension of federal aid, not even for scholarships and fellowships.

The members of this Commission seem genuinely fearful of the federal government. Despite the fact that they found no abuses in the British system of subsidies,[14] only one attempt at appointment control under the subsidy program to agricultural colleges (a study for the Commission), fine cooperation in federal grants, a willingness to concentrate research grants on institutions best fitted to carry the research through—despite all of this the Commission warned against any extension of federal aid. These conclusions seem to derive from a fear of federal control, and from an unwillingness to encourage further extension of federal activities.

Undoubtedly, the Commission fears government more than business; for it appeals to business to provide the main part of the few hundred million dollars

[13] *PC*, I, p. 41. *Cf.* my *The Market for College Graduates* (Cambridge, 1949), where I have discussed some of the issues raised by enrollments suggested by *PC*. Unfortunately, the Commission paid scant attention to this important problem.

[14] Studied in a separate volume for the Commission, H. W. Dodd, L. M. Hacker, L. Rodgers, *Government Assistance of Universities in Great Britain*, 1952.

additional required each year. Distrust of the federal government is especially germane in these days of investigations. But, as Hofstadter so well shows, there are also issues involved in the relation of IHL and its alumni and trustees.[15] It is important, as the Commission suggests, not to be dependent excessively on any one interest.

If the Commission is too coy vis-à-vis the federal government, the *PC* would strain the federal budget too much. Even before the Korean War, it would be hard to justify the additional federal outlays for higher education proposed by *PC*. What is more, the implications of *PC*'s proposals are a steady growth of public as against private IHL. In fact, since the funds would be made available primarily to public institutions, the enrollment in public institutions would rise to 80 per cent of the total by 1960, as against little more than 50 per cent in 1950.

Actually, the total contributions proposed for the federal government by *PC* are much greater than is suggested by the table above. In all, the federal government was to provide $844 million for general expenditures (as indicated by the table), $217 million for capital, and $1,000 million for scholarships and fellowships, or $2,061 million in all. On top of this, state government was to provide $1,000 million (as indicated in the table) and 433 million for capital. The total of all expenditures for higher education then rises to $4.3 billion. These amounts are, of course, out of the question at this time and were much beyond the practical even when proposed in 1947.[16]

It is scarcely necessary to add that the proposed burden on state governments would be intolerable. In 1951, total expenditures of state governments amounted to $15.1 billion.[17] Inflation, large tax drains of the federal government, and the growing distress of local governments excessively dependent on the general property tax have greatly strained state finances. In that year all expenditures of state governments for state institutions of higher education were $1,166 million. Of this total, $656 million were spent on current operation other than capital outlays.[18] This figure greatly exceeds the $445 million made available to public higher education in 1950 for current operation, the total given by *Millett* (p. 325), and hence includes some extraneous items. At any rate, an increase of current outlays from about $500 million to $1,000 million and of capital outlays from $289 (1951 total) to $433 million would almost double total outlays and raise state outlays for *all* purposes by 4 per cent. An increase of, say, 10 per cent of current and capital outlays (½ of 1 per cent of all outlays), however, is conceivable, and this might yield $75 million additional.

Both *PC* and the Commission suggested that charges of about 40 per cent

[15] R. Hofstadter and D. C. Hardy, *The Development and Scope of Higher Education in the United States,* 1952 (a Commission volume).

[18] *Ibid.*, p. 33.

of all income would overburden state and local governments. Indeed, the Commission recognizes the problems faced by state government, inclusive of the arrogation of major tax revenues by the federal government, the general rise of taxation, the pressure to increase outlays in other directions than education, in part because of the matching of some of these outlays by the federal government (*Report,* pp. 142-48).

C. Gifts and Endowment Income

With increased dependence on government aid ruled out by the Commission (with the exception of what state governments might spare), the only other important alternative for the Commission is greater dependence on gifts. The Commission recognizes that the inflation has wiped out a large part of the endowment. In fact, a combination of increased enrollment, higher prices, and reduced interest rates has reduced the contribution of endowment income per student; and higher taxes and the increased competition of other funds (*e.g.,* community chests, Red Cross, hospital, war) have resulted in a substantial reduction of the share of the Gross National Product going to IHL in the form of gifts in recent years as compared with the proportions received in 1900-1930.[19]

A measure of losses suffered is given by the fact that over a decade, the *value* of endowment in real purchasing power declined by about 50 per cent, or $750 million; and endowment *income* in real terms declined by 50 per cent, despite a rise in dollar amount by $700 million, or one-half. The percentage of educational income obtained through private benefactions was 5.6, 6.6, and 6.2 per cent of educational income in 1930, 1940, and 1950, respectively; but in real purchasing power per student there was a decline from 1940 to 1950 (*Millett,* p. 336). Endowment income as a percentage of *educational* income of private IHL actually declined from 31.2 per cent in 1930 to 25.5 per cent in 1940 and to 13.9 per cent in 1950. The contribution per student in real purchasing power has declined by about 60 per cent (cf. *Millett,* p. 307). The effects would have been much more serious had not the IHL shifted a substanial part of their investments from fixed interest bearing assets to common and preferred stocks and bonds. The resulting gains may, of course, prove illusory should a serious depression or a decline of values ensue. IHL have also profited from the development of a productive program of annual giving. But in general the annual contribution from gifts and endowment income are relatively much less important than they were twenty years ago.

In the light of this background, it is well to consider the major recommendation of the Commission, namely, that business corporations might be asked to contribute $250 million annually to IHL. It will be recalled from our earlier table that the actual contributions from endowment (13.9 per cent) and benefactions (6.2 per cent) were 20.1 per cent as against the contribution of 9 per cent from these two sources proposed by *PC* for 1960.

In 1950, the corporations contributed about $250 million in gifts of all

[19] For a discussion of some of these issues, see my *How Shall We Pay for Education?* (New York, Harper & Brothers, 1948), pp. 133-61.

kinds, of which IHL received 17 per cent, or about $45 million. All gifts were about 0.61 per cent of corporate income before taxes (*Report*, pp. 168-69). The actual cost to the corporation and the stockholders (assuming *ultimate* distribution of all income and unchanged taxes) was about 0.15 per cent of corporate income, with the federal government contributing the remainder through tax remissions. Additional gifts to IHL of $250 million would, therefore, involve a cost to the corporations and their owners of but $60 million, or roughly 1/10 of 1 per cent of corporate income before tax. The case for increased gifts is indeed strong, especially when consideration is paid to the direct and indirect contributions of IHL to the income of corporations.

But there are obstacles. Although corporate giving has increased by ten times since 1936, this rise is relatively little more than the gain in corporate income. Legal obstacles are important, though these are gradually being overcome. The experience of the medical schools in a well organized campaign is significant. This group raised but $3 million *in all* over several years, whereas the additional funds required by medical schools probably exceed $40 million per year.

Finally, the question as to the price to be paid has to be considered. In response to the plea made by the Commission, *Barron's*, in a lead editorial Jan. 1, 1953,[20] has replied to IHL that their financial trials are of their own doing; that their professors are responsible for full employment policies, inflation, higher taxes and controls; and that, if they want to prove themselves worthy, they had better dismiss their leftist professors. The editorial in *Barron's* does not, I hope, represent the general attitude of business. In fact, as President Conant said in his 1952 report, the *great* business benefactors have not set conditions. But it is also clear that as IHL seek for more funds from special interests, they may increasingly be pressed to yield control over educational policies.

Conclusion

IHL are in need of additional resources. The case for increased income rests on the failure to improve the quality of higher education in proportion to the over-all rise of material resources and standard of living; on the large relative deterioration of the economic status of the faculty; on the need of not relying excessively on tuition paid during school years; on the effects of higher taxation, inflation, lower yield on capital, and the rise of enrollment on the contribution of endowment and gift income per student.

The crucial issue is where to obtain additional resources. Whereas the Commission, fearing the federal government, urges greater dependence upon business and continued high tuition from students, the *PC*, impressed by the relation of economic resources to attendance at IHL and sympathetic to the extension of government aid, would rely on the federal government primarily and state government secondarily. The difference in approach rests partly on the fact that the Commission weights more heavily than the *PC* the noneconomic factors accounting for nonattendance at IHL, and also is more

[20] *Cf.* my reply, Jan. 29, 1953.

disposed to deny entry to IHL to those who might only depress standards. Those who are fearful of interference by both government and business, may find my suggestions for financing higher education congenial. This proposal would require the student to pay the entire cost of his education over his college and working life.

May I end by saying that the Report and the supplementary volumes are the most important study of the economics of higher education yet made available. No one interested in these problems can afford to neglect these volumes.

Elementary Algebra and the Equation of Exchange

During the six years since the close of World War II, twenty textbooks in the field of money and banking or money and business activity by American economists have been published.[1] With one exception, these books refer to the equation of exchange in discussions of the interrelationships of such concepts as the quantity of money, its rate of use, the level of prices, the quantity of goods and services sold, and the money volume of transactions. In all nineteen books, the equation is written in the traditional form, MV = PT, or in an equivalent form.[2] This appears to be an algebraic equation of the type $xy = wz$, or $x = \frac{wz}{y}$. However, if a reader attempts to treat the equation of exchange, with the definitions of the terms as they are given in these books, as an algebraic equation, and to substitute true numerical values (or approximations to such values), various difficulties turn up which ought not to appear when using a simple algebraic equation.

In two of the nineteen books it is pointed out that the term PT is a substitution for the term Σpq. However, in both cases the equation is developed in a form which attempts to add nonhomogeneous quantities, or measure a "meaningless heap," to use an expression of the late Professor Schumpeter.[3] Of the seventeen books in which the expression PT, but not Σpq, is used, two define P as an index number with an unspecified base, while treating the other three elements in the equation as absolute quantities. In two books, both P and T are defined as index numbers, with M and V absolute quantities. Any attempt to insert numerical values in the equation MV = PT by using these definitions and index numbers with a base of 1 or 100 (which are the only bases in common use) gives the absurd result of a figure of several hundred billions being equal to a figure of a few tens of thousands, or smaller.

[1] Books by persons from other countries now teaching in the United States are included. A list of the books may be obtained from the author.

[2] By "equivalent" form I mean a form which differs from MV = PT only by the use of other symbols for one or more of these four letters, or by the shifting of one or more of these four elements to the other side of the equation by using its reciprocal.

Some of the authors retain Fisher's distinction between currency and its velocity (MV) and bank deposits and their velocity (M'V'). This distinction will be ignored here; that is, M refers to all forms of money used as circulating medium, and V to the average velocity (number of uses per time period) for all transactions, or for purchase of final products.

[3] Joseph A. Schumpeter, *Business Cycles* (New York, McGraw-Hill, 1939), p. 484. The general concept of an assorted lot, or heap, of goods and services does, of course, have meaning, and so do the concepts of larger or smaller applied to two or more such heaps. However, quantitative measurement of such a heap, for use in mathematical formula, is without meaning unless a common unit of measurement, applicable to all the items in the heap, is specified.

To avoid a fallacious result, one of the books specifies that P, the index number of the general price level, represents the average price paid for the various goods and services, and that T is an index number of quantities with the unit of measurement of each class of goods a dollar's worth of that class in a base year. Two other books which do not refer to P and T as index numbers use the same procedure. While this procedure works out correctly, it is impossible to apply to factual data because it would require complete coverage and a knowledge, for every item, of the physical quantity which sold for a dollar in the base year. The basic methodology of index numbers, that of sampling, weighting, and expression of the results in the form of relatives to 100 for the base year, cannot be used; and the results of the procedure cannot properly be called index numbers.

Of the remaining books, one has no definition nor description of P and T, merely stating that the PT factor is the all-inclusive sum of money transactions in the period and may be subdivided into its parts. In all the others the phrases used in defining both P and T are ambiguous, and some of them are subject to the "meaningless heap" censure. In none of these cases would it be possible to find numerical values to fit the definitions without additional specifications, *i.e.*, without altering the definition.

In thirteen of the books, the equation, MV = PT, is described as a "truism" or "identity." With the ambiguous or inconsistent definitions used, this is not necessarily true: some of them, in fact, lead to false and absurd results when applied to numerical data. Moreover, only two of the books point out that for any time period payments for things (MV) are not precisely equal to the sum of the values of those sold (Σpq), because of debts carried over the ends of the period.

The reason for most of the inconsistent and inadequate definitions of the terms of the equation of exchange appears to be the general acceptance of the expression PT for Σpq. As indicated above, the latter term is not used in seventeen of the textbooks. Of the two authors who use both expressions, neither points out the important fact that the latter term cannot accurately be represented by the former. This obvious fact had been mentioned by at least one previous author of a money and banking textbook, Harold Reed. "Technically, of course PT is bad mathematical terminology. T refers, usually, to many commodities, to cloth, to corporate securities, to iron, to house rents, to labor. There is no homogeneous unit of T. It is impossible to add coal to cloth to corporate securities to iron to rents to labor."[4] Schumpeter had also emphasized the ambiguity and lack of meaning of expressions such as "the price level" except when defined in terms of the relative magnitude of Σpq for one period compared with another period, with an unchanged collection of goods and services.[5] Inasmuch as Reed's book was published four years earlier, and Schumpeter's seven, than any of the nineteen postwar texts on money and banking, it would seem that later writers might have taken a cue from them and avoided the ambiguous and inaccurate terminology.

[4] Harold L. Reed, *Money, Currency and Banking* (New York, McGraw-Hill, 1942), p. 144.

[5] Schumpeter, *op. cit.*, pp. 451-56.

All the authors use the equation of exchange in discussing changes in the value of money, or level of prices, over time. This implies an application of the equation of exchange to successive time periods. However, none of the authors develops the equation in a suitable form for this purpose, though this is easily done with very simple algebraic manipulations, starting with the correct form of the equation for a particular time period, $mv = \Sigma pq$.[6] The procedure is to use subscripts, o for the base year and i for later years ($i = 1, 2, \ldots$); then, since both sides of an equation can be divided by the same quantity (represented by either side of another equation), to write

$$\frac{m_i v_i}{m_0 v_0} = \frac{\sum p_i q_i}{\sum p_0 q_0}.$$

In this form both sides of the equation represent the relative aggregate value in the year i, in comparison with the base year, of the transactions to which the equation is applied. The money-velocity side of this equation can be rewritten in the equivalent form $\left(\frac{m_i}{m_0}\right)\left(\frac{v_i}{v_0}\right)$, *i.e.*, as simple relatives of the quantity and velocity of money. On the price-quantity side of the equation, we can multiply both numerator and denominator by the same quantity, selecting either $\Sigma p_i q_o$ or $\Sigma p_o q_i$. We then have

$$\frac{\sum p_i q_i}{\sum p_0 q_0} \cdot \frac{\sum p_i q_0}{\sum p_i q_0} = \left(\frac{\sum p_i q_0}{\sum p_0 q_0}\right)\left(\frac{\sum p_i q_i}{\sum p_i q_0}\right),$$

which is the Laspeyres formula for a price index with a Paasche formula for a quantity of goods and services index; or

$$\frac{\sum p_i q_i}{\sum p_0 q_0} \cdot \frac{\sum p_0 q_i}{\sum p_0 q_i} = \left(\frac{\sum p_i q_i}{\sum p_0 q_i}\right)\left(\frac{\sum p_0 q_i}{\sum p_0 q_0}\right),$$

which is the Paasche formula for a price index and the Laspeyres formula for the quantity index. If we do not like the combination of a price index which uses weights of the base year and a quantity index which uses weights of the current year, or the reverse combination, we can substitute for both indexes the formula recommended by Bowley more than a half-century ago, and later called by Fisher the "ideal" formula.[7] Other formulas may also be used. In each case the algebraic manipulations by which the chosen price index formula is introduced into the equation will provide a corresponding formula for the quantity index.[8]

[6] Lower-case letters are used here for the money-velocity side of the equation, as well as the price-quantity side, so that the capital letters can be used for the index number form to be developed.

[7] The simplest way of showing that this substitution can be made is to make it and then simplify the result, which will reduce to the original $\frac{\Sigma p_i q_i}{\Sigma p_o q_o}$.

[8] For an excellent brief discussion of various index number formulas and their origins see the article, "Index Numbers," by C. M. Walsh, in *Encyclopædia of the Social Sciences* (New York, Macmillan, 1932), VII, 652-58.

With the foregoing we can write MV = PT, defining all four of the terms as indexes to the same base, with M and V ordinary relatives and P and T index numbers based on the "ideal" formula or on some other selected pair of formulas. For practical application, price and quantity index numbers based on formulas which are not properly paired with each other, mathematically, may be used as approximations; even those derived by use of the "ideal" formula will also be approximations because of computation from samples rather than the whole universe of transactions to which the equation is applied.

There is another form of the equation of exchange, closely related to the foregoing, which is also of great use in dealing with the central problem of monetary economics, namely, the relation of the price level and monetary policy to business fluctuations. This form may conveniently be written $M_tV_t = P_tT_t$, with the terms defined as trend-adjusted index numbers, or percentage ratios to trend, and with the trends appropriately selected and interrelated. Selection of the trends is as follows: for T, the average rate of growth in output or physical volume of transactions over a substantial period of time (several "business cycles"); for V, the reciprocal of the average rate of growth (positive or negative) in holdings of cash balances (money) relative to aggregate expenditures for the type of goods and services included in T, also over a period of several "business cycles"; for P, none, on the ground that neither a falling nor rising price level is characteristic of a stable economy; and for M, the combined average rate of growth in output and in cash holdings relative to expenditures, on the ground that this is the rate of growth in the quantity of money needed for maintenance of economic stability, or maximum production, minimum unemployment, and a stable level of prices.

In view of the usefulness and simplicity of derivation of the index number and trend-adjusted index number forms of the equation of exchange, it is difficult to understand why monetary economists and economic theorists generally have neglected to make use of them, or why all the textbook writers either distort the Fisherine form of the equation by use of ambiguous or inconsistent definitions, or use definitions which are too clumsy or cumbersome for application to statistical data. It seems incredible that the appearance in American economic literature of the index number form of the equation, and its derivation, should have been delayed for several decades after Fisher's popularization of the equation, and that only one attempt has been made to utilize the equation in a practical way by developing a set of index numbers of all four of its elements.[9]

CLARK WARBURTON*

* The author is an economist in the Division of Research and Statistics, Federal Deposit Insurance Corporation. The opinions expressed are personal only.

[9] The earliest presentation of the index number form of the equation of exchange and its derivation with which the writer is acquainted is in a paper, "Comments on the Equation of Exchange," given at the Fifth Annual Conference, Indian Economic Association, Patna, India, December 1922 (*Proceedings* of the Conference, pp. 88-105). More detailed treatments of the relation of price and quantity index numbers to the theory of the value of money and the equation of exchange are given in François Divisia, *Economique Rationelle* (Paris, Gaston Doin, 1928), Ch. XIV, and in Griffith C. Evans, *Mathematical*

A Note on the Relationships of Bank Capital to the Lending Ability of the Commercial Banks

There has been published in recent months a spate of articles, pamphlets and monographs which have discussed the problems of bank capital.[1] Most of these take note of the very low ratio of capital accounts to assets or deposit liabilities.[2] In the samples which have come to my attention this is universally regarded as an unfavorable development from the standpoint of the longer-term interests of the bankers, their customers and patrons. The authors point with alarm to the fact that inadequate bank capital creates a condition inimical to the maintenance of depositor confidence, to the ability of the banks to absorb losses and still maintain their solvency—and lastly, that inadequate bank capital curtails the ability of the banks to supply their business customers with needed credit.

It is with this last "function" of bank capital that issue is here taken. Judged by the many variants of statements concerning the relationships of bank capital to the lending ability of the banks, the belief is apparently widely held that the capital accounts constitute a *source* of loan-funds; that commercial banks loan out the savings of the banks' owners.

Such statements are common and are to be expected in the trade journals, but when they appear in the more scholarly publications, or are authored by professional economists, they should not be allowed to go unchallenged. Four such statements have been selected for examination here.[3]

Introduction to Economics (New York, McGraw-Hill, 1930), Ch. IX. Index numbers of the elements of the equation of exchange for the United States for the period 1919-1947, quarterly and annually, are given in a paper, "Index Numbers of the Elements of the Equation of Exchange," presented by the writer at a joint meeting of the Econometric Society and the American Statistical Association, December 28, 1948 (available in mimeographed form; abstract published in *Econometrica*, Apr. 1949, XVII, 176).

[1] The terms capital and capital accounts are used synonymously. As so used they include the aggregate of capital stock, surplus, undivided profits and all net worth reserves.

[2] Bank capital as a percentage of total liabilities has declined, with minor reversals of the trend, for the past seventy-five years: from a percentage of approximately 35 in 1875 to about 7 as of the present time. The series is characterized by a number of sharp declines in the capital ratios with connected plateaus of relative stability. In the 1880's, for example the level was about 30 per cent as compared with about 20 per cent during the 1900-1910 period, and about 12 per cent in the 1930's. In the course of World War II, the ratio fell decisively below the 10 per cent level, traditionally regarded as a minimum for safety. Since the end of the war the capital ratios have tended upward, largely due to an expansion of bank capital accounts. This in turn is almost entirely attributable to retention of earnings.

[3] *The Increased Dependence of Business on the Commercial Banks*, Bull. No. 175, Institute of International Finance, The Schools of Business of New York University, Mar. 4, 1952, pp. 4, 5, 12, 19. Gaylord A. Freeman, Jr., *The Problems of Adequate Bank Capital*, Illinois Bankers Association, May 23, 1952, pp. 2, 5, 10, 13, 44, 47, 79, 80. Other examples could be cited from an article by Marcus Nadler, "The Trend of Commercial Loans," *Finance*, Jan. 15, 1952, see especially pp. 41, 42, 95. Similar misconceptions of the basic nature and distinctive character of the commercial bank as contrasted with all other types of financial institutions are to be found in many of our recent money and banking textbooks. See, for example, George W. Woodworth, *The Monetary and Banking System* (New York, 1950), p. 84, and Chart 70; E. W Boehmler, R. I. Robinson, F. H. Gane and L. C.

On page 12 of the bulletin published by the Institute of International Finance is the statement:

> If the need for working capital should grow it will create problems for the commercial banks, particularly for those whose capital is small in relation to deposits and risk assets. . . . Therefore, unless the banks take measures to expand their lending ability by increasing their capital resources. . . .

And at the end of the bulletin (pp. 18, 19, italics added):

> In view of the vital function banks perform in the economy and *the definite relationship between the capital resources of a bank and its ability to lend* it is important that banks be in a position to increase their capital resources either through retained earnings or the sale of stock in the open market. In this way the banks would be enabled to meet the increased requirements of industry and trade.

Similar notions are to be found in the monograph published under the auspices of the Illinois Bankers Association. On page 5, footnote 12, of this publication the author states:

> . . . if there is a continued growth of demand for credit the limited capital of many banks will prevent their providing the additional credit.

And on page 79:

> The principal function of capital is to . . . enable the bank to continue in business, and provide needed credit.

It is recognized of course that there are some relationships between bank capital and the ability of the banks to lend. This note is merely a denial that bank capital is a *source* of such funds.

State and national laws have long placed limitations on the amount any single bank can lend to any single borrower. Most of these limitations have defined these maximums in terms of a percentage of capital or of capital and surplus. However, such a limitation does not curtail the ability of the entire system of banks to make loans, except in a purely administrative sense.

Furthermore, supervisory authorities have tried, with virtually no success, to relate the volume of bank capital to the volume of liabilities, or of risk assets. To the extent that low capital ratios cause bank examiners to put pressure upon bankers to restrict their lending, it may be said that "inadequate" capital can lead to a denial of business loan applications. But the record shows that various "rules-of-thumb," including the venerated "10 per cent" criterion, have long since gone by the board. Unless supervisory authorities are much more successful in the future than they have been in the past in restricting bank lending to a definite ratio of capital funds it could not be concluded that bank credit is definitely tied to or limited by the volume of bank capital. Indeed if current trends are indicative, it seems probable that supervisory au-

---

Farwell, *Financial Institutions* (Homewood, 1951), p. 91; Jay L. O'Hara, *Money and Banking* (New York, 1948), p. 101; and Charles L. Prather, *Money and Banking,* 5th ed. (Homewood, 1953), p. 223.

thorities will put even less credence in "rules-of-thumb" and more reliance on qualitative judgments in determinations of the adequacy of bank capital.[4]

The foregoing should not be interpreted, however, as a denial that the expansion of capital accounts will not ordinarily increase the lending ability of the banking system, *but the increased lending ability derives from the fact that an expansion of the capital accounts, by causing a diminution of deposits in the system, releases excess legal reserves.*

While it is possible that capital accounts of banks could grow out of the investing of previously idle currency hoards, or from gold flights from other countries where the owners chose to invest their funds in new bank stock, these and other similar sources are extremely unimportant. For all practical purposes the only really significant "outside" source of capital for banks is the bank-held savings of bank customers. Consequently an expansion of commercial bank capital accounts tends to cause an equal reduction in the banks' deposit liabilities. The increased lending ability of the banking system therefore grows out of the release of excess reserves within the system.[5]

An expansion of the capital accounts of banks through the retention of earnings will increase the lending ability of the banks for the same reason since the retention of earnings tends to cause demand deposits to decline by the same amount that the equity accounts (undivided profits) are expanded. Thus excess reserves are released and on the basis of these the banks can, if they have the opportunity, create a structure of loan-deposits equal to the volume of earnings retained.

[4] Neither the supervisory staff of the Comptroller of the Currency nor that of the Federal Deposit Insurance Corporation adhere at present to any mechanical or fixed standard or ratio in gauging the adequacy of bank capital structures. Their practices, which are borne out by various public statements, indicate that they believe that a uniform standard would be applicable to only a few banks, and that the test of capital adequacy for any given bank should give consideration to the quality and nature of its assets, the quality of its management, and the general manner in which the business of the bank is conducted. See statement by Maple T. Harl, chairman, Federal Deposit Insurance Corporation, "What Are Proper Standards For Bank Capital?", *Banking*, Jan., 1952, xliv, 35. See also the *Annual Reports* of the Comptroller of the Currency and the Federal Deposit Insurance Corporation. For a summary of views and practices of state supervisory authorities see: *A Report of the Committee on Risk Asset Ratio Study*, New York State Bankers Association, Mar., 1952, especially pp. 17-22.

[5] These effects could easily be overestimated. If, for example, all holders of time deposits in commercial banks could be induced to buy new issues of bank stock this would not increase the lending ability of the banks by the volume of these deposits, but only a fraction thereof. Taking the 1952 year-end figure of approximately \$40.3 billion for the total volume of time deposits in all commercial banks and assuming an average reserve ratio of .05 required against these deposits we obtain a figure of \$2.0 billion as being the volume of excess reserves released if all time deposits were invested in new bank stock. On the basis of these excess reserves the banks could (*cet. par.*, including the public's holdings of currency and assuming an average reserve ratio of .15) create approximately \$13.3 billion in new loan-deposits. The formula for the above calculation is $L = C/R$, where L represents the volume of loan-deposits potentially creatable; C, the volume of excess reserves in the system; and R, the weighted arithmetic average of the reserve ratios applicable to demand deposits for all banks in the system.

It is impossible to make a similar estimate for demand deposits since the volume of these deposits held idle and regarded by their owners as savings is indeterminate.

Substantially the same reasoning applies to any given bank in the system. If the expansion of the capital accounts comes through the retention of earnings, the lending ability of the bank is increased because there has been a decline in the deposits of the given bank and/or other banks, thus causing an expansion of the bank's excess reserves. If the retention of earnings is at the expense of the customers of other banks, the bank's lending ability will be much more enhanced than were these earnings at the expense of the bank's own customers. Income derived from the customers of other banks adds to the total as well as the excess reserves of the bank, while earnings derived from the bank's own customers add nothing to the bank's total reserves. In the latter instance excess reserves are increased only a fractional part (around 15 per cent on the average) of such earnings.

If the capital accounts of a given bank are expanded through the sale of new issues of stock this will also cause a reduction in the deposits of the given bank and/or other banks, unless (which is unlikely) the stock is purchased out of currency hoards. The lending ability of the bank is again increased for the same reasons given above; viz., the release of excess reserves (where the owners of the new stock are customers of the given bank), or the expansion of total (and excess) legal reserves (where the owners of the new stock are customers of other banks).

Whereas the lending ability of a bank is increased more by the sale of bank stock to (or the derivation of earnings from) the customers of other banks, this advantage is at the expense of other banks with the result that, from the standpoint of the system, the lending ability of the banks is increased only to the extent (or less) that deposits are utilized (and thereby destroyed) in these operations. Even if it is assumed that the earnings retained, or the savings utilized in the purchase of new issues of stock, are entirely at the expense of the demand deposit, rather than the time deposit, holdings of bank customers, new loan applications can only be accommodated to the amount of these deposits.

Lest this equivalence be misinterpreted it is perhaps well to reiterate the well-established fact that commercial banks, in their lending or investing activities, create credit. And from this it has been repeatedly affirmed that the commercial banks do not, indeed cannot, lend out the savings of their depositors. From the foregoing discussion it should also be apparent that the commercial banks cannot loan out the savings of their stockholders, either voluntary or forced. But there is this difference: When a bank depositor saves and keeps his savings in the bank this simply results per se in *idle* deposits, but no change in either the volume or the composition of the assets and liabilities of the banks.[6] There is thus no change in the lending ability of the banks unless the depositor chooses to transfer these savings from the demand to the time category, or from a bank having a higher to a bank having a lower reserve ratio requirement.

[6] This action on the part of bank customers by reducing the turnover of funds dampens effective demands in the markets, and thereby tends to diminish the future opportunities of the banks to lend.

When a bank customer saves and puts these savings into new bank stock, or a bank stockholder has savings forced upon him by action of the board of directors, this causes a diminution of deposit liabilities and a corresponding increase in the banks' net worth accounts. Since reserves are only required against deposit liabilities this creates excess reserves in the system and consequently increases the lending ability of the banks. If the banks are able to take advantage of their new-found excess reserves they do so by accommodating borrowers (with immaterial exceptions) with newly created deposits. Thus it may be said that, in so far as borrowers are accommodated with deposits, the commercial banks originate all funds lent. They are not middlemen in the lending process for either depositors or stockholders.

Wicksell on Fiscal Reform: Further Comment

With its emphasis on Wicksell's benefit-*theory* of tax reform, Professor Buchanan's recent "Comment"[1] supplements what I had to say mainly about Wicksell's *practical program* of fiscal reform in my article.[2] Buchanan's discussion is an excellent summary of Wicksell's theory of "justice in taxation" as expressed in *Finanztheoretische Untersuchungen*. This summary, however, needs amplification on an important point because Buchanan neglected to mention the preconditions Wicksell regarded as necessary, and the existence of which he postulated in developing this argument, for his schema for "just taxation." These conditions were:

1. Intensively developed, democratic political institutions involving *inter alia* universal adult suffrage and elections on the basis of proportional representation, to the end that all minorities might achieve political representation, in proportion to their strength.[3]

2. An undertaking by parliament always to consider proposed expenditures along with the taxes necessary to support them and to allow minorities ample opportunity to veto and amend majority proposals which would not pass unless they received a qualified majority vote (of at least two-thirds, or more, if possible and practicable) of the members of parliament.

3. *A revision by gradual confiscatory taxation of some existing property relations and of the distribution of income and wealth so that the revised distribution might be sanctioned as "just" by a social consensus reflecting the contemporary sense of justice.* Among the property rights, types of wealth, and income he would have modified and subjected to confiscatory taxation were: (a) the then unlimited right to acquire property by inheritance, (b) monopoly gains of all sorts, (c) most varieties of "unearned" incomes and increments in asset values—particularly in land values in communities with increasing den-

sity of population, (d) value-gains that accrue, and abnormal concentrations of wealth that are frequently made possible for large property owners and entrepreneurs at the expense of small owners and of the propertyless, in the course of business fluctuations and as a result of sustained periods of inflation, such as occurred during the first World War and its aftermath.[4]

Given these conditions—and it is clear that with respect to condition (3) this was demanding a good deal—Wicksell was anxious to place all decisions concerning public expenditures and taxes (except taxes to cover interest and amortization on the public debt, for reasons given on page 600 and note 6 of Buchanan's "Comment") under the voluntarist principles of relative unanimity of consent by all parties in a thoroughly representative parliament. Because these preconditions were not even approximately realized during his lifetime, Wicksell found it necessary to agitate for political reforms to make them possible, and to support progressive income and property taxes. Although the latter were not a perfect answer to his quest for justice in taxation, they tended at least to remove the worst injustices perpetrated under the tax systems of his day. Those systems relied almost exclusively on indirect taxes enacted by parliamentarian majorities representing mainly the propertied classes because, until the close of World War I, the franchise was generally denied to the propertyless.

Wicksell's advocacy of the "confiscation principle" of taxation to obtain the desired revision of the distribution of wealth, was mainly intended (a) to eliminate all forms of rent from the category of private income and (b) to make restitution for and prevent the recurrence of the "capitalistic bolshevism"[5] that affects the distribution of wealth when the value of money is undergoing substantial change, especially during periods of inflation.

To the extent possible, Wicksell wanted to eliminate rent from private income by taxation, because income of this type can presumably be taken from individuals by the state without impairing their production incentives and without reducing the output of goods and services. Then the state in turn ought to use the corresponding revenues for a secondary distribution of social real income to all citizens in the form of an increasing variety and quantity of useful public or social services, especially in the fields of education and public health, for expansion of these services would provide greater equality of opportunity for all citizens, and they would also contribute both directly and indirectly to an increase in general productivity.

In order to reinforce the foregoing long-run aim by appropriate short-run action, Wicksell held that the pervasive changes in the distribution of wealth which are a byproduct of significant changes in the value of money should, so far as possible, be prevented. If they could not be prevented entirely, then

[4] Knut Wicksell, *Finanztheoretische Untersuchungen*, pp. 143-50.

[5] This descriptive phrase was coined by Wicksell's colleague, D. Davidson, in an article on "Valutaproblemets teoretiska innebörd" (Theoretical Implications of Problems Relating to the Value of Money), *Ekon. Tids.*, 1920, xxii, 83 ff. It referred to the progressive acquisition of wealth by the debtor class or enterpreneurs from creditors and rentiers that occurs in an inflationary period as a result of the decline in purchasing power of money. The more protracted the inflation, and the higher it spirals, the more thorough this form of "bolshevism."

upon the return of more stable monetary conditions, arrangements should be made for partial restitution of losses[6] to those who had been impoverished as a result of the preceding inflation (or deflation). To his mind, a money of stable value, *i.e.*, a nearly constant price level, was a prerequisite for rational economic conduct, especially with respect to individuals' plans or investments for the future. Moreover, this stability seemed essential to Wicksell for the protection and progress of democratic political institutions in society.

It is, of course, possible that Buchanan may be right in saying that because of the existence of strong, functional groups and because of the Keynesian impact on fiscal policy, Wicksell's voluntarist benefit-taxation-schema is "deserving of more careful consideration than when . . . first proposed."[7] Yet this seems rather improbable. A proposal that presupposes a "just distribution" is not much more applicable to our own than to Wicksell's world, not unless it can be shown that Wicksell was wrong about this precondition and that, in fact, his schema is applicable with net advantages regardless of the character of society's distribution of income and wealth. Thus far, this has *not* been demonstrated. Further, the contemporary fiscal problem also involves more variables than those Wicksell recognized in *Finanztheoretische Untersuchungen* (though he came closer to seeing most of them in his monetary analysis); hence its solution apparently requires a different approach and treatment from that which it received there.

CARL G. UHR*

[6] Wicksell's most explicit argument for the restitution scheme is found in the separate statement he made in a report to the Swedish government in 1920 as a participant in its Commission of Financial Experts, *"Bilaga till Utlåtande av 1920 Års Finanssakkunnige"* (Appendix to the Report of the 1920 Commission of Financial Experts), (Stockholm, 1920).

Domestic Air Line Self-Sufficiency: Comment

Mr. Harold D. Koontz, in two recent articles[1] has advocated the merger of the present sixteen trunk line air carriers into a system of six carriers.[2] That consolidation is essentially to be in the form of combining the twelve small carriers into two systems, while leaving the four largest carriers little changed.[3] Feeder lines are not considered.[4] The purpose of this note will be to analyze the argument on which Koontz bases his policy recommendation, rather than to examine that policy and the alternatives, if any, to it.

Koontz begins with an attempt to estimate the amount of the subsidy. He

[1] "Domestic Airline Self-Sufficiency," *Am. Econ. Rev.*, Mar. 1952, XLII, 103-25; and "Economic and Managerial Factors Underlying Subsidy Needs of Domestic Trunk Line Carriers," *Jour. Air Law and Commerce*, Spring 1951, XVIII, 127-56.

[2] *Review*, p. 124.

[3] *Journal*, p. 154.

[4] There are some 20 feeder or local service lines, the largest of which are about the size of the smallest trunk lines, measured in gross revenue. The classification is arbitrary; essentially those in operation prior to 1938 are classified as trunk lines, while feeders have entered the industry since the end of the war.

assumes that a service rate (*i.e.*, nonsubsidy rate) for the carriage of air mail would be the same as for the carriage of passengers.[5] It is difficult to see the reason for assuming that a mail rate yielding the same revenue per ton mile as the passenger rate is thereby somehow a nonsubsidy rate. The passenger service is sold in a mass market, in which, although there is often but one seller of the air line service, there is a broad group of buyers who choose air service as only one of several competing means of transport. In such a market, conventional pricing concepts are applicable. Mail, however, is transported under conditions approaching those of bilateral monopoly, with a single buyer of the service, the Post Office, and often a single seller, the air line serving the pair of cities involved. Nor is there even any relation between the postage rates which Congress establishes for the Post Office to charge the users of the air mail service and the rates which the Civil Aeronautics Board establishes for the Post Office to pay for the carriage of its mail. The price elasticity of demand for the carriage of air mail may well be zero. It is hard for me to see why passenger rates, an average of coach and first-class fares in continually variable proportions, even assuming that existing passenger fares represent optimum pricing in the various passenger markets being served, should somehow represent a norm for mail rates, which would appear to be a completely different market. In a bilateral monopoly situation, such as the relation between the Post Office and the air lines, there will be no market price in the usual sense, and price will be determined by bargaining. If subsidy is defined as payments in excess of market price, the subsidies are also indeterminate. As Locklin has argued, it is only in a special case that the Ernst and Ernst method is appropriate.[6]

Koontz shows that if the air lines had been paid for the carriage of mail on the basis he suggests, all lines would have been paid less, with a resultant decrease in net operating income.[7] In 1949 only the big four carriers would have

[5] *Review*, p. 105; *Journal*, pp. 128-29. Although Koontz sets forth no justification for his assumption, that assumption is perhaps derived from the report of Ernst and Ernst on the separation of compensatory mail pay from total mail payments ("Report of Ernst and Ernst on Survey of Separation of Compensatory Mail Pay from Total Mail Payments to Domestic Airlines," *Journal*, Spring 1951, XVIII, pp. 206 ff.) They write, "Since passenger and mail are the primary services, and are rendered jointly (passengers contributing more than 85 per cent of the total revenue and mail approximately 6 per cent), we believe that the compensation paid for both services should be related, varied only to cover the cost differential existing because of the exclusive passenger or exclusive mail costs involved" (*ibid*, p. 233). This represents, however, a statement of faith on the part of the cost accounting firm, and does not necessarily constitute a principle to be accepted without economic analysis.

[6] D. Philip Locklin, "A Critique of Proposals to Separate Subsidy from Air Mail Pay," *Jour. Air Law and Commerce*, Spring 1951, XVIII, 166-180.

That case requires that total air line revenues, including mail revenues related to passenger fares, be just sufficient to cover all costs including a fair but not excessive return on investment. Under conditions in which total revenues, including mail revenues so fixed, are greater or less than total costs, including returns on capital, the establishment of mail rates based on passenger fares is not proper, and the fixing of mail rates above the level of fully allocated costs based on market consideration will only constitute a subsidy if total costs of air mail service exceed the amount which the users would be willing to pay.

[7] *Review*, pp. 106-07.

been in the black; in 1950 half the lines would have been in the black. Koontz, however, regards 1949 as more normal than 1950,[8] even though most economic time series show a dip for the earlier year. It is this evidence of poor financial performance—that is, what would have been poor financial performance if passenger fares had been paid for the carriage of mail—that leads Koontz to search out its causes (other than his own assumptions) and make his policy recommendations.

There follows a section in which Koontz demonstrates that there are not substantial differences in the average cost per available ton mile of the sixteen carriers.[9] Available ton miles represent total transport capacity, some of which will be utilized, and some left to perish through underutilization. Presumably, however, air line management is producing revenue transportation rather than potential transportation, so that a more relevant calculation might have been average cost per revenue ton mile. But because the average cost per available ton mile does not show great variations between carriers, Koontz concludes that economies of scale are absent, although he points out later that it is variations in the load factor[10] which essentially account for the less favorable earnings in the commercial market of the smaller carriers.[11] This implies that perhaps a smaller proportion of seats are occupied on the smaller lines, which still further implies that possibly the unit is too large. I submit that the matching of the size of the productive unit, in this case the plane, to the size of the market, is one of the problems generally comprehended among those of economies of scale. It is also true, and the industry has shown considerable concern thereon, that no small modern aircraft, suitable to lightly trafficked routes, are available from American manufacturers. Smaller air lines thus are largely forced to employ units larger than can be filled by their traffic. But no amount of corporate merger will solve the technical problem of providing small, fast, and cheap aircraft for thinly trafficked routes.

Koontz then turns to variations in the effectiveness of management as a possible explanation for the variations of profits between carriers. He explains the profitability of Eastern and American as resulting, in part, from the offering of a high volume of frequently scheduled service.[12] If the profits of these two carriers are due to the size of their output, this hardly seems consistent with his statement on the preceding page: "When only the nine largest carriers are considered, evidence of any economies of scale virtually disappears."[13]

Koontz indicates that although there are wide differences in managerial effectiveness, such differences are insufficient to explain the differences in profitability. While that may sometimes be true, there may be other cases in which differences in managerial ability are important. For example, a simple test of managerial ability would seem to be its response to changes in the

[8] *Review*, p. 108.

[9] *Review*, pp. 108-14; *Journal*, pp. 133-40.

[10] *I.e.*, revenue ton miles divided by available ton miles.

[12] *Review*, pp. 114-15; *Journal*, p. 150.

[13] *Review*, p. 113.

volume of traffic. If output, measured in revenue ton miles, changes, one would expect an alert management to be able to change its costs in the same direction, although, of course, not necessarily proportionately. Thus if traffic declines, management, at least within the limits imposed by the indivisibility of the productive unit, the aircraft, should succeed in making some cost reductions; and likewise, above the minimum size, one would expect management to have to increase its costs somewhat when traffic rises. On heavily travelled routes the qualification of indivisibility may become unimportant.

A leading trade paper, *American Aviation,* publishes monthly data on air line traffic and expenses, taken from reports of the carriers filed currently with the Civil Aeronautics Board. During the period of relative price stability between January 1947 and the outbreak of the Korean War, carriers' cost figures can be used without the clear-cut necessity of a deflator, so that simple correlations of total operating expenses, in unadjusted dollars, and total revenue ton miles can be made for individual carriers. As just indicated, one would expect the well-managed carrier to show a positive relation between changes in revenue traffic and changes in total cost. For the period for which I have scrutinized the data, January 1947 to May 1950, twenty-nine observations or twenty-eight intermonthly periods, tightly managed and profitable Eastern had such a positive relation 20 times, and negative only 8. United had 17 positive relations and 11 negative. TWA, least profitable of the large carriers, had a positive only 13 times, and negative 15 times. Thus it was more often than not the experience for TWA, at least during those 29 months, to spend more when traffic declined and to cut expenditures when traffic rose. I think it can be said that differences of this magnitude in managements' responses to changed conditions may well be sufficient to account for the differences in profitability, at least as between the particular carriers mentioned. That difference in profitability had been substantial.

Koontz then suggests that load factor is the most important factor in financial self-sufficiency, and that high load factors may be obtained by serving major markets.[14] This may be another way of saying the aircraft in conventional use are too large for the market they serve at the existing price level. But let us examine a moment the first proposition: that high load factors mean profitability. Koontz' Table V, showing, for 1949 and 1950 for each trunk carrier, actual load factor and net operating income adjusted by his method, that is, by charging passenger fares to the mail load, is the basis for his assertion that improved load factors are the solution. He points out that most lines could have operated profitably, even after mail pay adjustment, if they had had the load factor of American, United, or TWA, about 58 per cent in 1949 and a few points higher in 1950. But he ignores his figures which indicate that Eastern operated profitably on a 46 per cent load factor in 1949; and 53 per cent in 1950. For 1949, the lines with higher load factors than Eastern's, but nevertheless with losses after mail pay adjustment, represent nine of the twelve other trunk carriers, though in 1950 only two were clearly inconsistent with his position. Thus, while load factors must be an important factor in profit-

[14] *Review,* pp. 117-22; *Journal,* pp. 144-45.

ability, other explanations cannot be discarded. The profitability of Eastern has still another aspect which is awkward for his thesis. He ascribes Eastern's profitability to its "policy of offering a high volume of frequently scheduled service."[15] There is nothing inconsistent with frequent service and low load factors, but can Koontz mean that most lines are profitable because of high load factors, and Eastern is profitable because of low load factors?

Koontz concludes that there is a high degree of correlation between large airlines and service in large markets, defined as the top 97 pairs of stations, in rank order of traffic generation. Such a conclusion would appear tautological, the same statistical unit, volume traffic, accounting for both large carriers and large traffic centers. It is, however, not inconceivable that the profitability of the large carriers serving large markets is due, to the extent that it is related to the size of the markets served at all, to the service of few small markets rather than many large. Koontz offers no direct evidence at this point.

There is, at any rate, still further room for question of his hypothesis: "The importance of having the high traffic density pairs of cities on a carrier's routes cannot be overestimated. Heavy travel brings favorable load factors, particularly where aircraft can be scheduled nonstop between the high traffic generating pairs of cities."[16] The exceptions to this proposition, as he indicates,[17] are TWA, National, and Western, which carriers served the so-called productive markets but did not get their "prorated share" as calculated in Table VI.[18] That failure to get the "prorated share" is ascribed to equipment shortages,[19] or in other words, a shortage on the supply side. If failure to get the "prorated share" of the market were due to such supply shortages, we would expect to find such supply as was available to be fully utilized. However, his Table V[20] shows the following load factors:

REVENUE LOAD FACTOR, DOMESTIC TRUNK AIR LINES
(per cent)

	1949		1950	
	Total	Passenger	Total	Passenger
Trunk line average	53.4	59.2	57.2	62.7
Trans World	58.4	60.9	61.0	65.4
National	37.5	44.9	47.2	53.6
Western	49.5	50.6	56.7	57.2

Thus, while TWA is above the industry average, National and Western are below. It is hard to believe that it is a shortage on the supply side that causes Western and National, at least, to sell a below average share of their available

output, and the reader might almost suspect that Koontz has confused demand and supply.

Since there seem to be certain deficiencies in the reasoning which underlies his diagnosis of the ills of the industry, it may be unnecessary to discuss here the merits of his policy recommendations. We might point out that it is his position that those carriers which are in difficulties are in that position because of the nature of the market they face; that is, the problem is one of demand. Will those problems be alleviated by the proposal to change the structure of the industry, that is, to make changes in the supply pattern?

It is, of course, always possible that a helpful prescription may nevertheless follow from a faulty diagnosis, and the merger program which Koontz advocates should receive, and has received, considerable attention. There is a great need for both careful analysis and fresh imagination with regard to our air transport policy.

JOHN P. CARTER*

* The author is associate professor of business administration, University of California.

Air Line Self-Sufficiency: Rejoinder

I welcome this opportunity to reply to Mr. Carter's interesting comments on my articles concerning the problem of financial self-sufficiency of the domestic trunk air lines.[1] It is gratifying to have these papers arouse such interest, although I wish that I might have found in my colleague's analysis more which would, in my judgment, contribute to the solution of the complex public policy questions involved in air line subsidies.

Except for Carter's point with regard to matching the size of the aircraft to the traffic available (an impracticable half-truth as will be pointed out), none of the comments he makes affects the validity of any of the conclusions reached in my article. Nor does he so claim in any of his detailed criticisms. Nevertheless, I should like to take the liberty of dealing briefly with certain of Carter's comments in the interest of clarifying aspects of my analysis which he apparently has misunderstood.

In the first place, Carter questions my use of the passenger return as a basis for measuring the extent of excessive mail pay and comes to the unchallenged conclusion that the actual extent of subsidy is indeterminate. It is exactly because this is true, as Ernst and Ernst found out after a long and expensive study,[2] that I chose not to devote my article to the futile task of exactly determining the amount of subsidy. As was clearly set forth in my paper, this assumption was made as "a working hypothesis" and "without presuming to decide what a service mail rate (*i.e.*, one free of an element of subsidy) should be."[3]

As I further made clear in using this assumption, I was employing what

[1] Although Mr. Carter makes references to another article written by me, his argument appears to be based on the paper in the *Review*.

[2] My assumption was made prior to the completion of the study of Ernst and Ernst.

[3] *Review*, p. 105.

might be regarded as a *maximum* service rate for purposes of clearing away some of the camouflage of excessive mail pay. Carter does not argue that this assumption vitiates the general validity of the net incomes resulting or the conclusions I drew. On the contrary, if there is more of a subsidy element than results from this assumption, my thesis is strengthened.

He questions my reference to 1949 as being a more normal year for the air lines than 1950. I fail to see how anyone familiar with the extraordinary traffic demands generated by the defense activities, which were expanded when the Korean conflict broke out in June 1950, can believe that 1950 would be more normal than 1949. Certainly no one in the air line business has had illusions on this point. However, using 1949 as a more normal year than 1950 for the air lines does not imply that air line traffic had reached its peak volume in that year. The point is rather that the sudden increase in demand for air travel, particularly over certain high traffic density segments, pushed load factors above that level which experience and service requirements have proved to be normal.

Carter prefers to use the revenue ton mile, rather than the available ton mile, as the statistical base against which to measure and compare operating costs of the various carriers, although he does not show that the use of this base would affect my conclusions. There is no unanimity among air line economists on this point, although most economists and statisticians in the industry feel that the available ton mile is the more accurate measure of what an air line produces, as a producing unit.[4] While any air line manager would naturally prefer a high volume of revenue ton miles (depending, of course, on the revenue per ton mile) to a high volume of available ton miles, the latter appears to be a more accurate basis upon which to compare operating costs because it is relatively independent of market factors.[5]

Suppose, for example, that air line A flies a Convair airplane at a direct operating expense of 80¢ per plane mile and air line B flies the same airplane under similar conditions at a cost of 60¢ per plane mile. Assuming a four-ton available load, the direct expense per available ton mile is 20¢ in the case of A and 15¢ in the case of B. But suppose that air line A happens to be operating in a dense traffic market and sells all its space while air line B operates in a more normal market and sells only an average of 60 per cent of its space. In this case, the cost per revenue ton mile would be 20¢ for A and 25¢ for B. From the standpoint of efficiency of operation, rather than from the point of view of fortuity of market, would Carter say that air line A is the more efficient operator?

Carter states that the problem of the smaller air lines operating over low density routes is not load factor but rather the managerial and technical one of matching size of the productive unit (the plane) to the size of the market. If it were not for the inexorable character of facts, Carter's point would be persuasive. No manufacturer of airplanes has yet been able to produce an air-

[4] For example, cost comparisons computed for industry use by the Air Transport Association employ the plane mile and the available ton mile as statistical bases of measurement. Most managements likewise use these bases for this purpose.

[5] In preferring the revenue ton mile basis, could Carter be confusing demand and supply factors?

plane which could conveniently expand and contract in size—and with a proportionate flexibility of operating expenses—to accommodate variations in passenger and cargo load between points on a flight, or times of a day, days of a week, or weeks of a year. One cannot deny that, if an airplane could be built which would carry few passengers as cheaply per passenger mile as those which carry many, much of the economic problem in air line operation would disappear. Ideally, the kind of flexibility envisioned by Carter would be gained by having single passenger airplanes which would operate as efficiently, as fast, and as safely as airplanes built for 40 or 50 passengers. Unfortunately for the air line industry, this is an impossible technical problem, largely because of certain basic facts of airplane design and air line operation.

While no manufacturer has tried to obtain the ultimate in flexibility—the efficient single passenger air line transport—in recent years practically every manufacturer has considered seriously airplanes of 15-20 passenger capacity, and several have spent millions of dollars on such development, only to find that these are economically impracticable for operation at the level of competitive rates existing in this country.[6] Because of certain minimum standards of safety, performance, and comfort, the minimum economic size of a transport airplane is sharply limited. A plane must have at least two engines, must have minimum characteristics of stability, and other minimums with respect to such equipment as radio, hydraulic and pressurization devices, and electrical systems. Thus, to build a 20-passenger airplane would cost approximately three-quarters as much as a 40-passenger airplane.[7] Moreover, there are certain operating costs beyond those related to the cost of the airplane (such as depreciation and maintenance) which tend to place a floor under economic size. Crew salaries and expenses are an important element of operating expenses and the requirements for passenger transport operation are a minimum of pilot, copilot, and cabin attendant. Thus the small airplane Carter relies upon for his matching of the unit with traffic would have practically the same crew costs per plane mile as a 40-passenger airplane.

Carter's point that a simple test of managerial ability would be its response to changes in volume of traffic has a certain degree of validity and is one well worth studying.[8] He shows, as between Eastern, United, and TWA, that Eastern had the best record on this score and TWA the worst. I have come to similar conclusions. But does his measure show the reason why Eastern was profitable and the twelve smallest carriers had far less profitable records? His observation, albeit interesting, has no particular bearing on the problem to which my paper was addressed.

[6] Some of the interesting failures in this class of airplane, all built since World War II, are the Lockheed "Saturn," the Beech 34, the Boeing 417, and the Northrop "Pioneer." Those interested in Carter's point would do well to study the economic and technical problems of these ventures. Even the successful Douglas DC-3 would never be built at today's manufacturing costs, its low plane-mile costs (which still are not low enough to give very favorable seat-mile costs) being due largely to the low capital cost involved.

[7] It is estimated that a 21-passenger DC-3, designed to present standards of safety and performance, would cost approximately $400,000 to build now compared to the selling price of a 40-44-passenger Convair liner of $540,000.

[8] As is noted below, because of competitive problems and service difficulties this however may not be as easy in practice as Carter implies.

Carter distorts some observations made as to variations in the effectiveness of management when he questions the consistency of my references to the "high volume of frequently scheduled service" of Eastern and American and my references to the generally small differences in the costs per available ton mile among the nine largest carriers. These being facts and not judgments, his comment is curious. As I stated in my paper,[9] there is some real question as to whether these cost differences should be as small as they are, except, of course, in the case of Eastern whose fairly low cost record I repeatedly mentioned.

Carter appears unclear about some of the economic characteristics of air line operation.[10] He finds the relationship of high volume of frequently scheduled service to revenue generation puzzling. He questions how the quality and volume of service offered (the "supply side") can affect the size of the market captured and how a carrier can be thwarted in obtaining its share because of equipment shortages. He feels that there can be no shortage of equipment if a carrier's load factor lags markedly behind the industry average and voices the suspicion that I may have confused demand and supply.

If the air line market were perfectly competitive, Carter's suspicion might be justified. But this is not the case, for it is obvious that air line competition is imperfect. Surely he has not forgotten that, under imperfect competition, the demand curve facing the individual firm can be shifted by the promotional action of the firm itself. It is one of the simplest facts of transportation that, where two or more carriers serve a market, the carrier offering superior volume and frequency of service has a marked advantage which is normally greater than the service difference.[11] Naturally an air line has difficulty in offering

[9] Note page 114 where I say, "It is difficult to conceive that most of the economies of size have been utilized when air lines reach the size of the small or medium small air lines listed in Tables I and II. It is certainly open to question that there should be so little difference in costs per available ton mile between air lines the size of Braniff or Western and those the size of American or United, which are seven to fourteen times as large. One gets the impression that . . . cost control is the more effective the more the need for it."

[10] I cannot comprehend his implication that I have argued that "most lines are profitable because of high load factors and Eastern is profitable because of low load factors." As pointed out throughout my study, Eastern is in some respects an exceptional case. In any event, Carter would surely not argue that, had Eastern's load factors been higher, its profits would have been less. Nor does he challenge the *essential* point made that the weaker carriers would have earned a profit, after adjustment for mail pay, had they been able to attract traffic adequate to bring about the load factors enjoyed by American.

[11] This is a familiar phenomenon in transportation and many instances could be cited to illustrate it if space permitted. While it has certain advantages other than frequency, the far greater frequency of service offered by the Pennsylvania Railroad than by the Baltimore and Ohio between New York and Washington has been a major factor in the higher *average* passenger loads of the Pennsylvania between these points. During 1949, National Airlines offered few through flights between New York and Miami, while Eastern offered many; naturally the travelling public utilized Eastern more than proportionately to the difference in schedule frequency. While there are service features other than frequency which attract passengers, frequency, as every air line sales manager knows, is one of the most important sales weapons. And many a railroad or air line passenger operator who sought to curtail expenses by reducing frequency has found to his sorrow that he suffered a greater than proportionate loss in traffic.

adequate service in a given market if it does not have the equipment to fly the necessary schedules.[12]

In the air line business, as in other similarly regulated industries, a management may not freely choose its market. Unlike businesses whose entry is relatively unrestricted by government, an air line cannot decide that, since the market facing it is thin, it will exploit a richer and more dense traffic area. It is free, of course, to apply to the Civil Aeronautics Board for admission to these markets and the Board's docket has been crowded throughout its history with applications of this kind. Even though the Board has granted a small percentage of these many applications for new routes and route modifications, its administration of a government policy of controlled competition has sharply limited the ability of the weaker carriers to enter many of the rich traffic markets of the larger and stronger carriers. If it were not for the restraining hand of government, these weaker carriers would take a page from the book of the noncertificated coach lines and attempt to enter the more profitable traffic markets.

If the weaker air lines are doomed to a subsidy existence because they cannot reach the heavy traffic-generating segments of the American economy, and thereby receive enough profitable traffic to offset losses on the thin traffic segments, the solution is obviously to open better markets to them. This can be done through abandonment of the present regulatory policy of controlling entry, or through remaking the route pattern and reallocating fewer routes on a more balanced basis, or through a wise program of combination. The last has seemed to me to be the most prudent course for public policy.

HAROLD D. KOONTZ*

[12] The concept and significance of load factor appears to have eluded Carter. The productive unit not being a perfectly divisible one, changes to meet shifts in demand between stations and between times of day and year cannot be made to the degree necessary to sell all available ton miles or seat miles, unless, of course, a "backlog" of passengers and cargo continually exist (a situation which is approached on some high density traffic segments.) Management is often sharply limited in its ability to curtail service in order to improve loads. A low load factor is often an indication of inadequate service, rather than of too much service.

Underemployment Equilibrium Rates of Growth: Comment

In his recent article,[1] Professor Eisner has endeavored to extend the work of Professor Domar by examining the nature of underemployment growth equilibria, as opposed to Domar's full employment equilibrium.[2] Despite his rather confident assertion that "would-be objectors to the theoretical concept

[1] Robert Eisner, "Underemployment Equilibrium Rates of Growth," *Am. Econ. Rev.* (March 1952), XLII, 43-58.

[2] *Cf.* E. D. Domar, "Capital Expansion, Rate of Growth and Employment," *Econometrica* (April 1946) XIV, 137-47; *idem,* "Expansion and Employment," *Am. Econ Rev.* (March 1947), XXXVII, 34-55; and *idem,* "The Problem of Capital Accumulation," *ibid.,* (Dec. 1948), XXXVIII, 777-94.

of underemployment equilibrium rates of growth . . . may . . . find little tangible to attack,"[3] a good deal, if not most, of Eisner's analysis seems subject to dispute. The points at issue are a series of misleading and questionable assumptions, some formal, others substantive, which cast considerable doubt on the validity of his conclusions. For convenience, we make the following comments under subheadings which refer to the appropriate equations and figures in Professor Eisner's article.

1. *Equation (17) and Figure (1):*

$$\frac{dP}{P} = \alpha\sigma\frac{Y}{P} \tag{17}$$

where P stands for productive capacity, α is a constant average (and therefore marginal) propensity to save, and σ represents "the ratio of the change in productive capacity . . . to the change in capital stock,"[4] which henceforth we shall refer to as the "productivity ratio."

Our first comment, which bears upon Domar's analysis also, concerns the reference to $\alpha\sigma$ as a full employment growth rate. This would be true only in the event that the growth in the labor supply is the same as the growth in capital stock. If the former is greater than the latter, it is clear that $\alpha\sigma$ will simply be a full *capacity* rate of growth only.[5] If the latter is greater than the former, as suggested by Domar,[6] it is also inconceivable that a growth of real income equal to $\alpha\sigma$ would provide full employment. For full capacity growth is clearly a necessary, if insufficient, condition of full employment growth. Nor can this problem be defined away (as Domar has tried to do) by having σ take account of additions to idle capital. Idle capital, unplanned, cannot accumulate indefinitely without severe repercussions on the rate of investment and employment. This point arises again in connection with Eisner's θ, so we shall defer further discussion of it for the moment.

More important, from the point of view of the present discussion, the Eisner analysis of underemployment growth equilibria, as shown in equation (17) and in each of his later, more complicated, cases, treats as constants variables which are actually functionally related to (even) long-run levels of income and employment. Specifically, the savings and investment coefficients, α and σ, are originally defined with reference to full employment. Eisner then proceeds to establish underemployment growth equilibria, as exemplified by equation (17), in which it is implicitly assumed that the full employment values of α and σ will obtain in the presence of underemployment. However, it is clear

[3] Eisner, *op. cit.*, p. 48.

[4] *Ibid.*, p. 44. Symbolically, $\sigma = \Delta Y/\Delta K$, ΔY being the change in (potential) real income or output and ΔK, the change in capital stock or (algebraic) net investment. Written in this fashion, σ is seen to be the reciprocal of the *accelerator*, $\Delta K/\Delta Y$, if the latter is represented *sans* lags. We shall have occasion to make use of these relationships in the discussion ahead.

[5] This distinction between full capacity and full employment growth and some implications have been discussed in my article, "Full Capacity vs. Full Employment Growth," *Quart. Jour. Econ.* (Aug. 1952), LXVI, 444-49.

[6] Domar, "Expansion and Employment," pp. 44-45.

that α, for instance, will tend to fall below its full employment values during periods of chronic underemployment. With the emergence of steady unemployment and excess capacity, with depressions drawn out and prosperities abortive (this is the significance for cyclical behavior of long-run underemployment), profits on the average will tend to be low; certainly they will tend to be much lower as a percentage of income during such periods than they would be in conditions of full employment. Dividends as well as speculative incomes will probably undergo severe contraction. Entrepreneurial and *rentier* incomes in general may be expected to decline as a fraction of income. These tendencies all point to a redistribution of income in favor of high (marginal) spending groups.

At the same time, σ, the productivity ratio, may tend to be higher during periods of underemployment growth than it would be during full capacity growth. In the presence of widespread unemployment, additional labor can be readily obtained to "work" the incremental capital. The ease with which other resources may be mobilized during chronic underemployment implies that the potential output associated with (net) investment will tend to be larger than it would be when the economy is confronted with full employment bottlenecks.

It is evident that an analysis of the forces which determine whether the economy will progress at full employment or suffer some sort of stagnation must take cognizance of the correlations between α and σ and the level of income and employment. The failure of Eisner to do this leaves his analysis of underemployment equilibrium seriously incomplete.[7]

But let us suppose that the values of α and σ under conditions of chronic underemployment could be established. Even then the validity of equation (17) is questionable. Eisner suggests that in underemployment equilibrium "the accumulation of capital . . ., because of its relation to the rate of growth, involves the creation of a constant proportion of excess capacity. . . ."[8] This statement is implicit in (17). It suggests that the increment in capital corresponding to a given increase in income must allow not only for the latter, but also for the maintenance of the constant proportion of excess capacity. But this leads to the implausible conclusion that the absolute amount of excess capacity will be permitted to get larger as national income rises, *despite the absence of any foreseeable use of the excess capacity.*

This last phrase is italicized because a certain amount of excess capacity is often maintained as a means of meeting peak demands in industries confronted with fluctuating demands. Also, in many of the basic industries and public utilities, where economies of scale are common, a certain amount of

[7] Contrary to Eisner's view (p. 50), the criticisms made of his diagrammatic equilibrium analysis need not necessarily apply to the Keynesian " 'saving-investment' curves of the current textbooks. . . ." For these curves may be appropriately drawn to show, for example, a declining marginal propensity to save and marginal propensity to invest as actual income falls below full employment levels and *vice versa*. And, of course, Keynesian analysis, being short run in character, ignores the σ or capacity-creating effects of investment.

[8] Eisner, *op. cit.*, p. 49.

overcapacity may be maintained in anticipation of future growth in demand.[9] Such overcapacity as this is, by definition, planned.[10] As such it differs fundamentally from the kind of overcapacity considered by Eisner. The latter kind, being the product of insufficient growth, of demand deficiency, is inherently unplanned.[11] Hence there is no reason why it should be maintained. Actually, it should have the effect of reducing the rate of (acceleration-induced) investment, thereby accentuating the underemployment tendencies.[12]

Under the circumstances, it is even difficult to envisage a steady, if underemployment, growth rate. A condition of underemployment may be taken as a situation in which a great many people are dissatisfied. This certainly is the significance of such things as excessive inventories idle plant and equipment, and involuntary unemployment of labor. Dissatisfied people may be expected to take action, action which may at first speed up the movement away from full employment, but which eventually will lead to reversal of the movement. We are thus back in the field of business cycle analysis. Steady growth rates involving underemployment, as are typified by equation (17), appear wholly inconsistent with the essential conditions of underemployment.

2. *Equations (19), (19a), (21), and Figure 2.* Professor Eisner seems to have sensed something of the problems raised by the use of "excess-capacity" term, θ. He has inserted a term into his investment equation (19a) to allow for the depressive effects of excess capacity. However, the form of equations (19) and (19a), and therefore implicitly (21), is open to question, both on the ground of economic content and on that of consistency. Reproducing these equations, we have

$$S = \alpha Y - \beta P \tag{19}$$

$$I = \alpha Y - \beta P \tag{19a}$$

$$\frac{dP}{P}\left(=\frac{I\sigma}{P}\right) = \left(\alpha\frac{Y}{P} - \beta\right)\sigma \tag{21}$$

We may first concentrate on (19a), the investment equation. It is not the growth in productive capacity (P) per se which depresses investment, but

[9] *Cf.* H. B. Chenery, "Overcapacity and the Acceleration Principle," *Econometrica* (Jan. 1952), XX, 1-11.

[10] In fact, if Y/P is used to denote this kind of excess capacity, equation (17) may be utilized to show full capacity growth which gives explicit recognition to it.

[11] To the extent that unplanned excess capacity can be used to meet planned requirements, its deflationary impact might be mitigated. Postulating this development as a generalization, however, would be tantamount to reducing the entire underemployment equilibrium analysis to a tautology.

[12] If it be argued that the kind of "excess capacity" conceived by Eisner in his Θ is the planned kind discussed in the text, then we would reply that violence is being done to the usual meaning accorded the term "excess capacity." In ordinary usage, the latter refers to capacity which is not desired, for which there is no use, which results only from the absence of better foresight, and most important, which is inconsistent with equilibrium. Additions to capacity made for reasons mentioned above are not excess capacity, and they are useless in explaining chronic underemployment. As one reader has well put it, the use of Θ to represent these planned increments in capital amounts to "slipping in Θ as a verbal disguise for a reduction in σ, but it does not represent any sort of illumination of the underemployment problem."

rather the growth of capital or capacity relative to aggregate output, *i.e.*, excess capacity, which does so. Use of the term P in (19a) probably stems from writings which claim a negative partial correlation between capital stock (or productive capacity) and investment. This view, however, overlooks the reason for this relationship, namely, the lag in the growth of income behind capital (the basic problem of the Harrod-Domar analyses), as a result of which excess capacity develops.[13]

Moreover, (19a) gives the impression that it represents an (admittedly simplified) investment function. Clearly, it is not. The attempt to make equations (19) and (19a) identical stems from the earlier Domar analysis in which the long-run saving-investment function αY is utilized. This function derives its plausibility from the Kuznets secular data showing (net) capital formation to have been a constant proportion of national income over long periods.[14] But the designation of capital formation as some fraction of income, αY, certainly does not mean that αY represents the "true" saving or, particularly, investment functions.[15] Any suggestion as a general proposition that at equilibrium the equality of planned saving and investment and/or planned and realized investment implies that these variables are functions of the same determinants is patently incorrect. Nevertheless, this is what is misleadingly implied by the elaborated short-run saving and investment equations represented by (19) and (19a). These equations notwithstanding, it is a simple matter to show that the equality of the quantities just mentioned implied by steady growth is attainable with saving and investment functions having nothing to do with each other.[16]

If it be argued that the equality of saving and investment assumed at the

[13] Nowhere is this oversight more important than in those discussions in which the marginal efficiency of capital is described as falling as the volume of investment increases. Such discussions, of course, take the level of income as a parameter. Should income increase in proportion to investment, however, it is clear that the resulting shifts in the entire marginal efficiency function would keep the rate of return unchanged as the volume of investment increases. *Cf.* my article, "The Accelerator in Income Analysis," *Quart. Jour. Econ.* (Nov. 1952), LXVI, 592-96.

[14] *Cf.* S. Kuznets, *National Product since 1869* (New York, 1946), p. 118. Actually, the fraction of real income thus saved displays a secular tendency to fall, a point ignored by many writers on saving and income.

[15] As will be shown below (p. 383), αY may be used to denote a long-run saving function.

[16] A simple first order difference equation may be employed in demonstration of this fact. Assume the income model

$$Y_t = (1\text{-}\alpha)Y_t + \lambda(Y_t - Y_{t-1}) \tag{a}$$

where λ is the annual accelerator. This equation has as its solution

$$Y_t = \frac{(\ \lambda\ )^t}{\lambda\text{-}\alpha} Y_o \tag{b}$$

where Y_o is the initial income and must be given. If we assume that $\lambda = 2.5$ and $\alpha = .1$, $\lambda/\lambda\text{-}\alpha$ has a value of .04. This means that if income grows initially in equation (a) at the compound rate of 4 per cent a year, this steady growth will be maintained. At the same time, saving and investment will be equal, even though the former is a function of the income *level* and the latter of the *change* in income.

outset of the discussion makes it permissible to identify the investment function with the saving function, then it may be asserted with equal force that the two functions should take the form of the investment function. Thus equation (19a) may be rewritten in some form such as

$$I = \lambda\Delta Y - \beta\frac{P}{Y} \tag{19b}$$

The first term on the right hand side of (19b) represents acceleration-induced investment, λ denoting the accelerator. P/Y is the ratio of productive capacity to income (output); it replaces the misleading "P" term of (19a). Equation (19b) has the advantage of according completely with the Harrod-Domar models, which are based on the accelerator.[17] In the event that (19b) were adopted, Eisner's equations (16) and (21) would have to be modified thus (remembering that λ is the reciprocal of σ):

$$dP \equiv \frac{I}{\lambda} = \Delta Y - \frac{\beta}{\lambda}P/Y \tag{16a}$$

$$\frac{dP}{P} \equiv \frac{I\sigma}{P} = \frac{\Delta Y - \beta\sigma P/Y}{P}$$

$$= \frac{\Delta Y}{P} - \frac{\beta\sigma}{Y} \tag{21a}$$

While (19b) may not be the only alternative to (19a), it does seem more realistic as an investment equation.

[17] That this is so may be shown as follows:

Write $$I = \lambda\Delta Y \tag{c}$$

then $$\Delta Y = \frac{I}{\lambda} \tag{d}$$

From the formula for the multiplier, $\Delta Y = \Delta I/\alpha$, it follows that

$$\frac{\Delta I}{\alpha} = \frac{I}{\lambda} \tag{e}$$

or $$\frac{\Delta I}{I} = \frac{\alpha}{\lambda} \tag{f}$$

So long as the average and marginal propensities to save are equal, it may be shown that $\Delta I/I = \Delta Y/Y$; cf. Eisner, *op. cit.*, p. 45. $\Delta Y/Y = \alpha/\lambda$ is the Harrod version of the growth formula. But if λ is the reciprocal of σ, then we may write $\Delta Y/Y = \alpha\sigma$, the Domar version of the formula for full capacity growth. Parenthetically, it might be noted that in the event of a disparity between the average and marginal propensities to save, the growth of investment necessary to achieve the "required" or "warranted" growth of income will be a *multiple* of the latter. Thus if s is the average propensity to save and α the marginal propensity, we may write $\Delta I/I = \alpha/s\ (\Delta Y/Y)$. Since, if anything, $\alpha > s$, $\alpha/s > 1$. This proposition may be proved by making the proper adjustments in Eisner's equation (5), *loc. cit.*

The reader's attention is also drawn to the use made of the reciprocal of Eisner's "employment ratio" Y/P. In this way, the second term in (19b) will get larger and investment smaller as the ratio of productive capacity to income (*i.e., excess* capacity) increases. This is in accord with Eisner's objectives.

Turning now to equation (19), the saving equation, two brief comments upon it are pertinent. In the first place, making saving (or consumption) a function of productive capacity as such seems untenable; there is no way in which saving can be related to *potential* output, which is what P symbolizes.[18] Nor would a term such as βP provide an answer to the "difficulties encountered in attempts to derive a long-run saving function from time series data."[19] There would still remain the problem of explaining why saving rises in a constant proportion to P. Such explanations as the Duesenberry "Veblen effects" and/or the Kuznets-Smithies effects of the population growth, urbanization, and new products are still needed.

Secondly, there seems to be a redundancy in Eisner's reasoning in connection with equation (19). This equation ostensibly drops the assumption that saving is a constant proportion of income, αY. Further, the constant in the typical short-run saving function is replaced by the trend term βP. This trend term gives formal expression to "the hypothesis that there is no long-run change in the proportion of income saved."[20] If this is true, it would appear that we are back where we started. This is the same as saying that in the long run, saving rises along a linear saving function which passes through the origin, implying that the ratio of its coordinates and its slope, *i.e.*, average and marginal propensities to save, are the same. This is precisely what the saving coefficient, α, initially implied, for α, in the term αY, is a long-run constant average (and therefore marginal) propensity to save. αY is merely a short-cut representation of a more elaborate short-run saving function which contains a trend term describing the familiar secular downward drift of this function.[21] The upshot of this is that, fundamentally, equations (19) through (21), as Eisner has presented them, do not appear to constitute a net advance beyond equations (16)-(17) if α is correctly interpreted.[22]

[18] However, it might be possible to relate saving indirectly to a (negative) term such as P/Y. Thus if a value for this ratio much greater than unity were to be used to denote chronic unemployment, the depressive effects on the savings coefficient of chronic unemployment discussed earlier might be interpolated into a saving function containing the term P/Y. Eisner has done just this in his equation (22), though using the reciprocal of P/Y and hence making it a positive term.

[19] Eisner, *op. cit.* p. 53.

[20] *Loc. cit.*, footnote 9.

[21] A graphical illustration of this secular drift of the short-run saving function along a long-run function through the origin is to be found in J. S. Duesenberry, *Income, Saving and the Theory of Consumer Behavior* (Cambridge, Mass., 1949), p. 114. See also P. A. Samuelson, "Full Employment after the War," in S. E. Harris, ed., *Postwar Economic Problems* (New York 1943), p. 35. Though both actually deal with the consumption function, the appropriate adjustments are easily made.

[22] The only way of obtaining a saving function containing a constant marginal, but variable average, propensity to save is with a linear function which intercepts the S axis below the origin; such a function is indicated by Eisner's equation (18). Proceeding within Eisner's own framework, it will be seen that if (18) is also used to denote the investment equation and is subjected to the same kind of differentiation process as that indicated in Eisner's equations (16) through (17) (p. 51), the results will be identical with those of Eisner's first model (p. 51), because of the disappearance of the constants in the course of differentiation. Thus a model based on the stated objectives of Eisner's second model (equations (18)-(21)) yields no different results from those of his initial model.

Most of the comments made in connection with equations (19)-(21) apply equally to Eisner's equations (22) and (22a). Hence we shall not undertake a detailed analysis of the latter. However, his insertion of a term (Y/P) into (22) to show the effects of stagnation on the long-run saving function is a point of interest to income analysts and stagnation theorists alike.

D. HAMBERG*

In connection with this point, the reader's attention is drawn to the difference in reasoning between Mr. Wagner and myself, despite the fact that we have both concluded that the βP term in Eisner's equation (19) vitiates his assertion that he has dropped the assumption of equality between the average and marginal propensity to consume. As a matter of fact, I find myself in agreement with Eisner's reply to Wagner, *viz.*, that equation (7) specifies an equilibrium condition, while (19) specifies a saving schedule or function; hence though P be a function of Y in (7), this certainly is not true in (19). Nevertheless, on the grounds I have argued, (19) does implicitly make the average and marginal values of the saving function equal. (Note the similarity between Eisner's reply to Wagner and my objection to Eisner's making savings and investment functions of the same things as a result of the equality of savings and investment in equilibrium.)

* The author is assistant professor of economics at the University of Maryland.

Underemployment Equilibrium Rates of Growth: Further Comment

Mr. Eisner, in his article in the March 1952 issue of the *Review*,[1] discusses three cases of the determination of equilibrium rates of growth. The first case assumes that the average propensity to save (APS) equals the marginal propensity to save (MPS). An equilibrium rate of growth implies an equilibrium "ratio of income to productive capacity (or 'employment ratio')" (p. 52). However, using this conception of equilibrium, Eisner is not entirely correct in stating, when he takes up his second and third cases: ". . . we drop the assumption that investment is a constant proportion of income but we retain a constant marginal propensity to save." As we shall see, APS $\doteq$ MPS in all three cases when either equilibrium[2] or any given employment ratio Y/P exists.

His equation (18) is the traditional savings function:

$$S = \alpha Y - b.$$

Since b is a constant, obviously APS $\neq$ MPS. But Eisner modifies (18) by substituting βP for b.

However, in equilibrium[3] P is *not* a constant; rather it is a function of Y,[4] as stated in equation (7) in the article:

[1] Robert Eisner, "Underemployment Equilibrium Rates of Growth," *Am. Econ. Rev.* (March 1952), XLII, 43-58.

[2] Refer to equations (7), (7a), and (8), *ibid.*, p. 46.

[3] If one considers the employment ratio as given $\widehat{\Theta} = Y/P$, the subsequent analysis follows analogously when $\widehat{\Theta}$ is substituted for Θ.

[4] Note that Eisner is perfectly correct in stating that APS is not a constant proportion of income if both Y and P are considered independent variables of the savings functions (equations 19 and 22). But in a position of equilibrium as defined in the article, Y and P are not functionally independent; in Eisner's words, ". . . if we start from a position of equilibrium such that $Y_o = \Theta P_o$, maintenance of equilibrium requires that $\Delta Y = \Theta \Delta P$" (p. 46).

$Y = \theta P \qquad [0 < \theta \leq 1$, the equality holding in full employment$]$.

Hence equations (19) and (22) should be rewritten:

$$S = Y\,(\alpha - \beta/\theta) \qquad (19^*)$$
$$S = Y\,(\alpha\theta - \beta/\theta) \qquad (22^*)$$

From these equations one can simply prove that APS = MPS:[5]

$$\text{MPS} = \frac{dS}{dY} = \alpha - \beta/\theta \qquad (19^{**})$$

$$\text{APS} = \frac{S}{Y} = \alpha - \beta/\theta \qquad (19^{***})$$

$$\text{MPS} = \alpha\theta - \beta/\theta \qquad (22^{**})$$

$$\text{APS} = \alpha\theta - \beta/\theta \qquad (22^{***})$$

Since MPS is assumed to be a constant, then α, β, and θ are constants; hence we conclude that APS is also a constant.

As a consequence of the equality of the marginal and average propensities to save, Mr. Eisner's algebraic manipulations for deriving equations (21) and (23) can be simplified. One need only substitute the above values of MPS (or the equivalent APS) for α in equation (17) of the first case. The substitution is justified since the first case assumes APS = MPS, and this note has shown that the same equality exists in the second and third cases when either equilibrium prevails or an employment ratio is specified.

HARVEY M. WAGNER*

[5] As a result of the equality, Mr. Eisner's use of α may be confusing. In his first case, α = MPS = APS. If Y and P varied independently, then α = MPS in the second and third cases also. But in an equilibrium context, α is merely a parametric constant $\neq$MPS = APS. (See footnote 4.)

Rejoinder

I welcome this opportunity to attempt to clear up what seem to me to be certain grievous misunderstandings of the arguments set forth in my "Underemployment . . ." article. These misunderstandings relate, I fear, not merely to my own work but to our general theories of growth of income and determination of the level of income at a given time.

Reply to Wagner. Wagner's departure from my analysis stems from his statement that "in equilibrium, *P* is *not* a constant; rather it is a function of *Y*." My equation (7), that $Y = \theta P$, is merely a formal description of "equilibrium" as I have defined it. It is most assuredly *not* a statement of how *P* may be expected to vary in relation to *Y* (or vice versa). The crux of the whole problem of economic growth as discussed by Domar and Harrod, as I

hoped I had suggested in my own brief comparison of their models, is that there is no reason to be confident that this "equilibrium," either of Domar's full employment variety or of the underemployment varieties constructed by Harrod and myself, would be maintained. Harrod, indeed, goes to great pains to indicate that growth equilibria are essentially unstable, and in so doing, lays the groundwork for the Hicksian model of the trade cycle. An essential purpose of my article was to clarify the implications of a hypothetical maintenance of a constant rate of growth. I was most certainly not indicating that our economic system is characterized by any such constant rate.

Hence it is quite at variance with my analysis to assume that such a constant rate exists and then to rewrite our traditional economic functions on the basis of that assumption. Specifically, we are accustomed to stating that saving is a function of income. Occasionally we choose to add certain other variables, as I have done, and say that saving varies in some relation to changes in these other variables. However, it is certainly foreign to the notion of a saving function to relate the variation of saving to changes in income under the rigid assumption that income remains a constant proportion of productive capacity. This of course, *can* be done, and I shall point in a moment to some value that may come from such a relation. But, I believe, to refer to such a relation as a saving function, or to refer to the derivative of saving with respect to income, obtained from such a function, as the "marginal propensity to save," as has Wagner, is to do violence to our tools of analysis.

The point to which Wagner might better have called attention is as follows. If σ is constant, that is, if the increase in productive capacity accompanying units of investment remains constant, maintenance of a constant employment ratio (income divided by productive capacity) at a fixed rate of growth requires that saving (investment) remain a fixed proportion of income. However, this assuredly does not mean that the marginal propensity to save *is* constant. For, expressing saving as a unique function of income, we would have to say that the curve representing this function on the two dimensional income-saving chart moves as productive capacity changes. The slope of this (moving) income-saving curve at any moment of time is the marginal propensity to save and it *is* constant in my equations (2b), (18), and (19). In equation (22) the marginal propensity to save ceases to be constant; partial derivation reveals quickly that $\frac{\partial S}{\partial Y} = \frac{2\alpha Y}{P}$. In none of the cases other than the most simple one, in which, by assumption, $S = \alpha Y$, does the marginal propensity to save equal the ratio of saving to income (Wagner's "average propensity to save"). Far from confirming even the constancy of the proportion of income saved, my departure from the simplified function (2b), $S = \alpha Y$, should suggest that this constancy is dependent upon the satisfaction of the conditions of growth which I have defined as "equilibrium." To allow the saving function, or the marginal propensity to save, to be defined by the condition of equilibrium which I have assumed, would be no more appropriate than to define the saving function in the Keynesian model, to which I have

tried to make my system analogous, as the (moving) intersection of (moving) saving and investment curves.[1]

Reply to Hamberg. The essential part of my answer to Hamberg must be to call attention again to my article and to the articles of Domar from which my own analysis is an offshoot. For, though objecting to my "misleading and questionable assumptions" (as well as those of Domar), Hamberg shows evidence of failing to understand the nature of those assumptions. By misinterpreting definitions and symbols he devotes much of his comment, curiously, to charging me with ignoring just those aspects of the problem to which much of my article was explicitly directed:

1. In his "first comment" Hamberg claims that $\alpha\sigma$ is "a full employment growth rate . . . only in the event that the growth in the labor supply is the same as the growth in capital stock." He reveals here an unfortunate confusion as to the meaning of σ. For as Domar has defined it, and as I reminded readers in my article, σ is the ratio of the change in productive capacity in a period of time to the change in capital stock which takes place in that period of time; it is the change in capacity which *accompanies,* not the change in capacity which *is caused by* a change in capital. Symbolically, σ is $\frac{\Delta P}{\Delta K}$, not $\frac{\delta P}{\delta K}$. What Hamberg apparently has in mind is $\frac{\delta P}{\delta K}$, the familiar marginal productivity of capital.[2] As I pointed out in my article, "The wording of this definition [of σ], it should be noted, is such that σ may well be a function of other variables than investment. In particular, increases in population which involved increases in the supply of labor would raise the value of σ."[3]

Thus, if productivity per worker were growing at a 2 per cent rate as a result of capital investment, change in technique, and all other factors, and if the labor supply were growing at a 1 per cent rate, the aggregate growth in capacity (or the full employment rate of growth) would be 3 per cent (more exactly, of course, 3.02 per cent). And this, in Domar's terms, would be precisely $\alpha\sigma$. This might have been viewed as a combination of the factors, $\alpha = .2$ and $\sigma = .15$. Now, if the rate of growth of the labor supply were to increase to, say, 3 per cent, this would in no way destroy the correspondence between $\alpha\sigma$ and the capacity rate of growth of income. Rather, the value of σ would be increased. For the increase in capacity accompanying each unit of investment would now reflect, in addition to the direct results of the

[1] On a minor point which I hope the foregoing makes irrelevant, I fail to see why Wagner claims that his note enables us to derive my equations (21) and (23) more directly. These equations were each "derived" in one step, by simple substitution. Wagner's development would seem, in addition to being spurious, to have actually certain undesirable qualities of roundaboutness.

[2] Curiously, this is exactly the confusion warned against by Domar. See, for example, his "Expansion and Employment," *Am. Econ. Rev.,* March, 1947, XXXVII, 40, where he cautions: "σ should not be confused with other related concepts such as the traditional marginal productivity of capital."

[3] P. 44, fn. 2.

investment itself (the marginal productivity of capital) and the other factors increasing productivity per worker, the 3 per cent increase in the labor supply. The capacity rate of growth of income would thus be 5 per cent (more exactly, 5.06 per cent), and assuming that the value of α remained .2, the value of σ would have been raised from .15 to .25.

It should be understood that the basic point of the Domar model is simply that growth in *capacity,* but not necessarily growth in *output,* accompanies investment. Growth in capacity will be more if other factors, such as an increasing labor supply, operate conjointly with investment to increase capacity. In order for full employment to be maintained, actual output must grow as fast as capacity, a "capacity" which presumes full utilization of all resources including labor. My own departure consists of exploring the consequences for the level of employment of rates of growth other than the rate necessary to maintain full utilization of capacity.

The possibility of underemployment of labor when capital is fully utilized is very likely a real one, but it is a problem of an essentially different nature from those tackled with the Domar model. The Domar problem is to raise demand at a rate equal to the increase in capacity. Hamberg says, in effect, that even if demand does increase at this rate something (structural maladjustments in the economy?) will prevent complete utilization of the labor supply. Presumably, increases in aggregate demand would result in price inflation of investment goods, and for some reason no change in the relative prices of investment goods and of labor would take place to bring about absorption of the increased labor supply. It is possible to explain this within the framework of a model of a stationary economy. It certainly might be true that in an economy with a continuously increasing labor supply, frictions and lags might prevent complete absorption of any given increment of labor before the next increment were thrown into the market. This, however, is all quite outside the basic model used by Domar and by me. Hamberg is not correct in finding any inconsistency on that account in our tools of analysis.[4]

2. Let us consider next Hamberg's criticisms of me for assuming "implicitly . . . that the full employment values of α and σ will obtain in the presence of underemployment." First, I do not see how Hamberg can assert that "it is clear that α, for instance, will tend to fall below its full employment values during periods of chronic underemployment." I wonder if he has not confused α, the marginal propensity to save out of income, with the proportion

[4] I cannot see why Hamberg relates underemployment to an excess of the rate of growth of the labor supply in relation to the rate of growth of capital. There seems no reason to assume that this kind of structural unemployment might not occur if the labor supply were growing less rapidly than capital, or even if the labor supply were not growing at all. (For example, locational, technological, or productwise changes might bring on underemployment which could not be ascribed to a deficiency of aggregate demand.)

It should be stated, in fairness to Domar, that he does consider the possibility that it will be physically impossible to attain the full capacity rate of growth (defined to involve full employment) in "The Problem of Capital Accumulation" (especially pp. 782-84), which Hamberg cites but to which he does not specifically refer. Domar's concept here may well be related to the ceiling to the rate of growth which plays such an important part in the Hicksian trade cycle.

of income saved. His reference to redistribution in periods of low income suggests that a lower proportion of income will be saved as unemployment increases—exactly what my functions (19) and (22) were used to demonstrate.[5] If, in fact, Hamberg has in mind the proportion of income saved, I must reply that I certainly have not assumed, implicitly or otherwise, that the full employment value of this proportion would "obtain in the presence of underemployment." The main burden of the latter part of my paper was to show how the proportion of income saved may vary with the proportion of underemployment and what some of the effects of this variation might be.

I have no objection in principle to Hamberg's hypothesis that σ may not be a constant.[6] My own presentation was intended to offer simple first approximations to the relationships under consideration. It would certainly be in order to examine the implications for the system of improving on these approximations on the basis of further theoretical or empirical considerations. It may be well, however, to evaluate carefully Hamberg's particular observation that σ may tend to be higher in periods of underemployment than during full capacity growth, in the light of Domar's discussion of the difference between σ and s.[7] Hamberg's observation may perhaps be more appropriately restricted to s, the increase in capacity relating to units of investment taken by themselves, abstracting from the possible loss in capacity resulting from displacement of existing capital stock which the new units of capital make uneconomical to operate.

3. In objecting to a concept of growth which "involves the creation of a constant proportion of excess capacity," Hamberg would appear to be misconstruing a tool of analysis as a statement about reality. I nowhere indicate that I believe that any economy can be expected to grow with a constant proportion of excess capacity. Indeed, my basic approach, in common with that of Harrod, Hicks and Domar, is that the equilibria presented would in fact be most difficult if not impossible to maintain. As emphasized in my article, Harrod's "warranted rate of growth," for example, to which my

[5] Indeed, I used considerable space in the original article, much more than it might be appropriate to employ for reiteration, to describe "low levels of investment during periods of unemployment" (p. 54 and p. 54 n), "dis-saving necessary to care for the unemployed" (p. 55), and "investment as a function of income, productive capacity and the employment ratio" (Figure 3, p. 56).

Hamberg's reference "to a redistribution of income in favor of high (marginal) spending groups" in a period of underemployment strikes me as uncertainly grounded empirically, but even more doubtful in terms of theoretical relevance to his assertion that the *marginal* propensity to save declines during periods of unemployment. It would seem quite probable that "high spending groups" maintain their high spending in the face of such adversity by borrowing and using past savings. This would hardly involve a low *marginal* propensity to save. But more important, individual or family propensities to save out of disposable income cannot be directly aggregated to obtain functions for the economy as a whole. The increased proportion of income absorbed in unemployment compensation and relief and the redistribution of income itself would both bring a sharp drop in saving as income and employment drop—hence a high aggregate *marginal* propensity to save.

[6] *Cf.* p. 44, fn. 3.

[7] *American Economic Review* (March, 1947), XXXVII, 39-40 and *Econometrica* (April, 1946), XIV, 143-45.

"equilibrium rate" is kin, is explicitly in *un*stable equilibrium; the slightest departure in either direction would set in motion forces accelerating the movement from equilibrium.[8]

Hamberg observes that "a condition of underemployment may be taken as a situation in which a great many people are dissatisfied," the result of which may be to "speed up the movement away from full employment." While not directly relevant to my model, this observation does deserve some comment in so far as it is, in effect, an unwarranted rejection of Harrod's "warranted rate of growth." I can see no valid reason for objection to the notion that a certain amount of aggregate underemployment is consistent with a situation in which some entrepreneurs are disappointed, others are satisfied, and still others achieve results which exceed their expectations. If such a situation can exist, there seems no a priori reason to reject Harrod's hypothesis that there is *some* rate of growth which (at a given time[9]) would induce entrepreneurs to behave in such a way that this rate of growth would be continued.[10] Hamberg might reject this hypothesis by asserting that there are relevant discontinuities in the function relating the aggregate *ex post* rate of growth and resultant behavior, or by asserting that the only rate of growth which would result in such behavior must involve full (or more than full?) employment. In either case, such rejection, without substantial supporting evidence and consideration of the conclusions of analysis by recent writers in the area of growth as well as the more traditional Keynesian underemployment presentation, would appear rather dogmatic.

4. Much of Hamberg's criticism of what he refers to as my "investment equation" is based on a terminological confusion. Like Keynes in the *General Theory* and Harrod and Domar, and like the United States Department of Commerce, I define *ex post* investment as identically equal to *ex post* saving; this equality is not dependent upon any equilibrium condition. My saving functions relate the amount of saving that would be *realized* at different levels of income and/or the other relevant parameters. The marginal propensity to save is hence not what society would like to save out of an increase in income but what it would actually save (in a schedule sense) if that increase were to take place (while other variables remained unchanged). If we then divide investment into "desired" and "undesired" components, it follows that saving is identically equal to the sum of "*desired* investment" and "*undesired* investment." The "*undesired* investment" may be most easily

[8] Pp. 48-50. My suggestion of "little tangible to attack" referred specifically to my endowment of "equilibrium" with no more than an unstable and largely definitional character. Hamberg's interpretation of this to mean that I "confidently" considered my article or any part of it beyond scientific criticism does credit neither to his nor to my epistemological awareness.

[9] The qualification "at a given time" is, I believe, mine rather than Harrod's. It suggests perhaps a more appropriate criticism of the concept of an equilibrium rate of growth: granting that such a rate exists, may it vary capriciously from moment to moment with exogenous variables such as expectations, politics or the state of the weather?

[10] See R. F. Harrod, *Towards a Dynamic Economics* (London, 1948), p. 82.

understood if considered to be excess inventory accumulation.[11] It is "*desired* investment" which Hamberg must be talking about when he discusses investment functions and refers to "the equality of saving and investment in equilibrium."

It should hardly be necessary to assert, in the year XVII since the *General Theory*, that planned or desired investment and actual saving are not "functions of the same determinants." I might add that this assertion need not rule out the possibility that the level of desired investment does have *some* effect on the proportion of income saved. Thus there is no need to retract the thought implicit in footnote 10, p. 54, that the amount which businessmen want to invest may actually influence the proportion saved out of a given income. For example, this influence is highly significant in the case of corporate saving and investing, where the saving and investment may be in effect identically equal for the individual saver-investor. We might even (!) ascribe *some* role to the interest rate in making the proportion of income saved a function of desired investment (and hence, indirectly, a function of the existing stock of capital and productive capacity).

Definitions do not, of course, alter substance and we could reach the same conclusions as I have (perhaps with more difficulty[12]) by using Hamberg's definitions. Thus, we might state that by investment we mean Hamberg's desired investment, the magnitude of which is determined by the acceleration relation. We could argue further that the equality of saving and desired investment is the condition for continuance of any given rate of growth. (We would here be ignoring the problem of encouraging growth by making saving always less than desired investment.) Then, in order to maintain any particular rate of growth, the level of income and the proportion of underemployment must be such that the amount saved would equal the amount of desired investment. We could thus assert, as does my article, that the proportion of underemployment related to any given sustained rate of growth depends upon the functions determining the amount of saving and the productivity of saving. Or we might state, as does my article, that once the saving and productivity parameters are given, the underemployment ratio is determined by the rate of growth. The system may be summarized briefly as $f(\alpha, \beta, \sigma, Y, dY, P) = 0$; expression in this implicit fashion has the virtue of implying nothing about the causal relations of the parameters. The function can then be made explicit to bring to the fore whatever parameter we should like to make dependent or otherwise the focus of attention.

5. Hamberg's comments on what he interprets to be my *ex ante* saving function are, I believe, partly answered in section 4, above: the saving function or schedule in my model would be the same, *ex ante* and *ex post* (any

[11] These relationships are presented more fully in my "The Invariant Multiplier," *Rev. Econ. Stud.*, 1949-50, XVII (3), 198-202. See also Lloyd A. Metzler, "Three Lags in the Circular Flow of Income," in *Income, Employment and Public Policy* (New York, 1948), esp. pp. 18-20.

[12] As it stands, Hamberg's equation (21a) is not useful for describing the relationships between rates of growth and underemployment with which my article is concerned.

difference between *ex ante* saving and *ex post* saving or investment would flow from a difference between *ex ante* and *ex post* income rather than a difference in the schedules). However, I remain puzzled by criticism that I should make saving (investment) a function of the productive capacity-income ratio rather than productive capacity alone, only to note Hamberg's admission (fn. 18) that I have done just that.[13]

Hamberg's objection to my equation

$$S = \alpha Y - \beta P \tag{19}$$

may perhaps be dismissed by reminding the reader that he has been willing to accept an equation using the term "P/Y" (19b).
For (19) can easily be rewritten:

$$S = Y\left(\alpha - \beta \frac{P}{Y}\right) \tag{19'}$$

Then saving may be viewed as a function of income and of the ratio of productive capacity and income. Dividing through by Y, we have

$$\frac{S}{Y} = \alpha - \beta \frac{P}{Y} \tag{19''}$$

indicating that the proportion of income saved is a function of the ratio of productive capacity to income (nothing more than the reciprocal of my employment ratio).

While I see nothing "wrong" with equation (19), I have no objection to passing over it to equation (22) which makes more explicit the relation between saving and the employment ratio. My main purpose in introducing (19) was expositional, to offer a more gradual transition from the simple function where, as in the Domar model, saving is a constant proportion of income.

Hamberg's charge that equations (19) to (21) in effect retain the assumption that saving is a constant proportion of income reflects a serious methodological issue, perhaps compounded with an inadvertent repetition of Wagner's error. It would appear to me useful to distinguish between that portion of saving which is a function of income and those portions which can be significantly related to other variables. The hypothesis that saving (or consumption) is related only to income is clearly one of limited usefulness (as some of our recent ill-fated predictors of national income will certainly testify). However, Hamberg's statement that my equations (19) to (21), and by later inference (22) as well, leave the marginal and average propensities to save equal is true only under some *ceteris paribus* assumption which, in effect, relegates other variables (in this case, productive capacity or the employment ratio) to oblivion. Indeed, this may be accomplished most simply by subjecting the

[13] Hamberg seems to feel that he has made some significant change in my Y/P term by inverting it and changing the sign. Actually, in an abstract model of this kind, where the main content given to relationships goes no further than the signs of partial derivatives, a change such as this is of no substance; its chief effect that I can see is to take attention away from the underemployment (employment) ratio to which I tried to call attention by using the relationship in the form Y/P.

saving function to the constraint of the "equilibrium" rate of growth condition as did Wagner. Hamberg declares himself in agreement with my objection to Wagner on this point. Yet, without Wagner's (improper) assumption of equilibrium my saving functions will meet the test Hamberg prescribes in the beginning of his footnote 22. Thus if

$$S = \alpha Y - \beta P, \tag{19}$$

on the common two-dimensional graph which Hamberg has in mind for relating saving and income, we have indeed "a linear function which intercepts the S axis below the origin"; the S-intercept is, of course, $-\beta P$ (that is, when income is zero, saving equals $-\beta P$). With Wagner's assumption that $P = \frac{Y}{\theta}$—an assumption that Hamberg rejects—this S-intercept assumes the value of zero (of course, if $P = \frac{Y}{\theta}$, when $Y = 0$, $P = 0$). It is difficult to see how Hamberg can both agree with my objection to Wagner's criticism and claim that I have retained saving functions which kept constant the proportion of income saved.

ROBERT EISNER*

N. Jasny's "The Soviet Economy during the Plan Era": A Correction

I regret the occurrence of a serious error in my review of this work.[1] Jasny's measurement of Soviet social accounts in terms of United States dollar prices of 1926-27, about which I had expressed certain misgivings, is not as heavily relied upon by the author as I had mistakenly assumed. It is, in fact, confined to his evaluation of the total *outputs* of various economic sectors, such as industry (broken down into consumers' and producers' goods), agriculture, and construction, and to an appraisal of investment outlay and its chief components. In each case a parallel valuation in terms of *Soviet* prices of 1926-27 is given, and the final structure of national income, as it emerges from Jasny's calculations, is entirely based on these prices.

Serious as this error may be, it does not, I think, materially affect the validity or relevance of my observations concerning the danger of using "esoteric" price structures in Soviet national income analysis. While Soviet prices of 1926-27[2] are not of course esoteric to the postwar Soviet economy in a *spatial* sense, they still suffer from a remoteness in time which is greatly aggravated by the intervening process of industrialization. In fact, the unprecedented violence of this process may well have rendered them quite as inapplicable as the prices of distant, but industrialized, America. Jasny is of course fully aware

[1] *Am. Econ. Rev.*, Mar. 1953, XLIII, 185-89.

[2] I refer here to the *actual* prices of that year as estimated by Jasny, and not to their conventional substitutes as used in Soviet statistics.

of these difficulties and his choice of the 1926-27 Soviet price pattern in preference to those of other years or other countries was not made without a good deal of critical examination, but the doubts which I ventured to express in my review concerned the general principle of such price imputations in the Soviet context compared with other methods of eliminating bias, where these can be used. Once the principle is conceded, Jasny must be deemed to have used the material available to him to the fullest advantage, subject to the qualifications concerning the estimation of composite price trends which I advanced in my review.

F. Seton

BOOK REVIEWS

Economic Theory; General Economics

Wesley Clair Mitchell, the Economic Scientist. Edited by Arthur F. Burns. (New York: National Bureau of Economic Research. 1952. Pp. viii, 387. $4.00.)

One of the things that serves in a small way to offset the loss of an outstanding personality in any scientific field is the realization that his passing will probably be followed by the publication of a memorial volume. One can then look forward to the intellectual delight of contemplating the whole of an illustrious scientific career. This has now come to pass with respect to Wesley Clair Mitchell, for whom Professor Authur F. Burns has prepared this memorial volume. Part I of this book, entitled "Life and Work," includes a lengthy introductory sketch by the editor, a delightful personal sketch by the late Professor Mitchell's wife, and a number of professional sketches and memorial addresses. This material reveals to the outside world the unique qualities of Mitchell's personality, the feeling of lofty purpose which dominated his life's work, and the inspiration which he gave to all his associates.

The appraisals of Parts II and III are attractively introduced not by the original titles of the articles, book reviews, and chapters selected for inclusion in this volume, but by new titles chosen by the editor. The early appraisals deal with Mitchell's "Place in Contemporary Economic Thought" (P. T. Homan), his "Contributions to the Theory of Business Cycles" (J. M. Clark), and his "Views on the Scope and Method of Economics" (A. B. Wolfe). The recent appraisals cover Mitchell as an "Economic Theorist" (Milton Friedman), an "Economic Naturalist" (E. B. Wilson), an "Historian of Economic Thought" (T. W. Hutchison), a "Social Scientist and Social Counselor" (A. H. Hansen), and as a "General Economist" (J. A. Schumpeter). The limitations of space do not permit an extended discussion of these various appraisals of Mitchell's work. It may be pointed out, however, that, as far as the major appraisals are concerned, the pros and cons are equally divided. The short commentaries of E. B. Wilson and T. W. Hutchison, which are in the form of book reviews, while interesting do not raise any major issues. Favorably disposed toward Mitchell are Clark, Wolfe, and Friedman, while somewhat inclined in the opposite direction are Homan, Hansen, and Schumpeter. Following Burns' suggestion, Friedman develops the interesting thesis that Mitchell's cycle analysis can be readily restated in the modern vocabulary of propensities, multipliers, acceleration coefficients and the like. Unfortunately for his own side of the case Clark plays somewhat into the hands of the opposition by stating in his appraisal that Mitchell emphasizes the "how" rather than the "why" in his cycle analysis. Wolfe's excellent appraisal is the only one that draws attention to the integrative philosophy which lifts Mitchell's work far above the level of the ordinary.

Leading the opposition, Homan's facilely written appraisal says in effect that, if institutionalism were worth cultivating (which is not the case, Homan believes), Mitchell, being without originality and philosophical grasp (p. 190), was not the one for the job in hand. The highlight of Hansen's two-pronged appraisal is the assertion that Mitchell's deficiencies as a social scientist are carried over into his views as a social counselor. Hansen's position is that, since Mitchell largely ignored the investment-saving problem, as a social counselor he failed to appreciate the value of "monetary and fiscal policies, as possible stabilizing and expansionist factors operating upon a mixed society . . ." (p. 316). There will be those who do not accept Hansen's interesting argument, asserting that Mitchell's totalistic approach quite logically fostered similarly broad views in the field of economic reform. In his appraisal Schumpeter brings up the rear guard of the opposition with the observation that Mitchell was really an equilibrium economist in spite of himself, who unfortunately was dazzled by the glitter of what Schumpter calls the "dubious Veblenite gems." It is apparent that there is a wide intellectual gulf between Schumpeter and Mitchell reflecting the basic differences between their respective mentors, Eugen von Böhm-Bawerk and Thorstein Veblen.

The various aspects of Mitchell's work are respectively seen by the reader through only the eyes of the single economist whose appraisal has been selected for inclusion in this volume. For example, there are not two or three different economists' appraisals of Mitchell's "place in contemporary economic thought." This reviewer would be much happier if readers had been given an opportunity to consider Mitchell's place in the stream of economic thought from a variety of points of view. And the same criticism applies to all the other appraisals which deal with the various facets of Mitchell's work from the point of view of only one critic.

In his prefatory note Burns explains that he did not permit his scientific sympathies to influence his selection of appraisals. He made every effort to make room for the views held by representatives of different schools of thought. There are commentaries from institutionalists, Keynesians, marginalists, and others not so easily classified. But each topic is not appraised from the points of view of these different schools. A really effective treatment would have called for appraisals from different points of view of each of the aspects of Mitchell's work listed by the editor. The reader would then perhaps be in a better position to make up his mind about Mitchell's work and to arrive at that "just and balanced appreciation" of Mitchell which the editor says in his prefatory note he hopes the reader will achieve.

The over-all effect of these appraisals must be somewhat disconcerting to many readers. They learn from Burns that Mitchell was quite aware of the value of equilibrium price theory (p. 47), but from Schumpeter that Mitchell would throw this theory "overboard" (p. 328). They are told by Friedman that Mitchell had all the elements of modern cycle theory in his own analysis of the cycle (p. 271), but by Hansen that Mitchell was concerned with measurement and description but not explanation of the cycle, and also at times showed "no recognition or grappling with the problems of investment

and saving (p. 315)." The reader is also informed by Schumpeter that Mitchell "never advocated 'policies' " (p. 326), but by Hansen that Mitchell's policy recommendations were too "radical" and "drastic" (p. 317). Homan tells the reader that Mitchell did not have an original mind (p. 186), while Clark asserts that Mitchell's work was of the "formative type" (p. 193), which presented a significant challenge to orthodox theory. Anyone thoroughly acquainted with Mitchell's attainments will wend his way through this curious maze of contradictions without any trouble. But what of the great majority of readers into whose hands this volume will fall sooner or later? Are they to conclude that Mitchell was a chameleonlike character about whose color one could never be quite certain?

The eight appraisals in this volume make little mention of the deep unity which runs through all of Mitchell's scientific interests. He had a highly integrated personality which was solidly rooted in a clear-cut philosophical position. His pragmatic philosophy, drawn from a number of different sources and distilled in his essentially independent mind, shows up everywhere—in his scientific method, in his theory of human nature, in his views on the scope of economic science, in his grasp of the interrelations of the social sciences, and in his attitude towards economic reform. It seems to this reviewer that a balanced appreciation of Mitchell can be secured only if the reader has brought to his attention the ways in which Mitchell's philosophical position binds together all that he did. Acceptance or rejection of his philosophical position is not the issue here. It is, instead, how can one secure a satisfactory understanding or appreciation of Mitchell? The answer obviously is: only by uncovering the basic unity which nourished all of Mitchell's scientific interests, and by tracing this unity throughout his scientific attainments.

The unity in Mitchell's work is not difficult to uncover. It runs through his business cycle analysis, his theory of capitalism, and his analysis of the problems of economic welfare. What Mitchell set out to do in the field of economics is quite clear. He wanted to enlarge the area of economic analysis until it became a "comprehensive study of economic behavior." The older studies, by which Mitchell meant equilibrium economics centering in price theory, should be added to until a broader economics emerges. The first step in this widening process was the development of business cycle theory; the next step was the working out of a theory of capitalism. The third step was to show the public-policy implications that flowed from his theory of capitalism. This trinity of Mitchell's interests may be separated for purposes of critical analysis, but for that "just and balanced appreciation" of Mitchell to which Burns refers, it is necessary to consider the three portions of Mitchell's work as parts of a larger whole. It is true that this trinity of interests did not receive anything like a well-rounded treatment by Mitchell. In this volume Friedman picks out a full-fledged theory of the cycle from what he describes as Mitchell's business-cycle "grab bag." It remains for someone to piece together in a similar manner the mosaic of Mitchell's theory of capitalism. His totalistic theory of the economic order is only fleetingly referred to in this volume (pp. 37 and 71). How much richer and more valuable to the general reader this volume would

have been had it included an essay on Mitchell's theory of capitalism, partially developed though it was. And the same can be said of Mitchell's theory of economic reform.

How did Mitchell view his own work? The answer to this question is given in the correspondence published in this volume for the first time, in which Mitchell states that "what I think is worth while is to accomplish some of the necessary pioneer work toward the construction of useful economic theory" (p. 66). This pioneering attitude toward the tasks to be accomplished was both an asset and a liability. As an asset it led Mitchell to look beyond the confining boundaries of orthodox economic thought, and to follow paths which promised more light on the economic problems of the first half of the twentieth century. But, as a liability, this pioneering attitude led Mitchell to pay little attention to the finished constructions of the general treatise and the polished refinements of the technical theorist. Although there may be some support for the view that Mitchell remained too long a "pioneer," still there can be no doubt but that he has won for himself an important and enduring place in his science's hall of fame.

ALLAN G. GRUCHY

University of Maryland

Einführung in die Wirtschaftstheorie. III. Teil, *Geld, Kredit, Volkseinkommen und Beschäftigung.* By ERICH SCHNEIDER. (Tübingen: J. C. B. Mohr [Paul Siebeck]. 1952. Pp. vi, 220. DM 17.00; paper, DM 14.00.)

With the publication of the third volume of his *Einführung*, Professor Schneider has completed his endeavor to present to his readers "all tools of theoretical reasoning that are needed for an analysis of the economic realities around us" (p. iii). His work, in this reviewer's opinion, constitutes one of the most comprehensive, most up-to-date, and pedagogically most serviceable of modern texts in economic theory.

The first volume, entitled "Theory of the Circular Flow in the Economy," appeared in 1947 and was reviewed in the September, 1949 issue of this *Review.* The second volume, on "Economic Plans and Economic Equilibrium in the Market Economy," appeared in 1949 and was reviewed in the September, 1950 issue. The third volume is about "Money, Credit, National Income and Employment." It deals with "macro-economics" (p. 2) in contrast to the second volume, which dealt with "micro-economics"; and it presents *ex ante* analysis in contrast with the first volume, which was largely confined to *ex post* analysis. (Looking backward, this reviewer has some doubts about the necessity or expedience of devoting so much space to *ex post* analysis, and he wonders whether the author would not have arranged matters somewhat differently if he had known *ex ante* all that he now knows *ex post.*)

The present volume is divided into three chapters. The first is on "The Means of Payments in our Present-Day Economy"; it is only seven pages long. The second chapter is on "The Creation and Cancellation of Money" (80 pages); the third is on "The Determinants of National Income and Its Fluctuations" (123 pages).

Schneider is ultramodern in every part of his text. He is ruthless in his treatment, or rather nontreatment, of old-fashioned theories or obsolete institutions. That the chapter on Money and Banking does not include the traditional discussion of the silver standard and of bimetallism is probably all to the good; but there is not a word about the gold standard either. This neglect, I am willing to concede, of a currency system that no longer exists is admittedly preferable to the customary overemphasis on, and long-winded exposition of irrelevant details of, the gold standard. (Excessive attention to institutional detail has prevented many textbook writers from noticing that even the United States and Switzerland have long abandoned the gold standard.) But in a textbook a discussion of the "creation of money" that does not have anything to say about gold can hardly be considered complete. The word "gold" does not appear in the index; it does appear twice in the text—together with foreign exchange and securities—when the essentials of open-market policy are explained (pp. 54 and 73); but there is no discussion of purchases or sales of gold by the banks or monetary authorities, of possible effects of changes in the official price of gold, of restrictions in the gold market, of the consequences of gold hoarding.

One cannot say that this contempt of past, recent, and current history is due to any aversion to institutional "facts" on the part of the author. That he has no such aversion he shows, for example, by the two pages on the present German banking law which he includes in the exposition of the principles of multiple expansion of bank credit. When he omits something from his discussion, he obviously does so because he thinks it is not important. He makes this explicit in his reference to the quantity theory of money (which he does not regard as worthy of discussion in the analysis of money and banking, but reluctantly includes as a brief digression in the exposition of national income formation). "Velocity of circulation" is referred to with obvious scorn; transactions velocity of circulation of money is not mentioned anywhere in the text; income velocity is accorded one page, chiefly to prove its irrelevance on the ground that it is "no institutionally determined constant" (p. 168). I do not know why this should make it irrelevant; but, as a matter of fact, its upper limit is probably institutionally determined and, indeed, this ceiling velocity plays a significant, though only implicit, part in Schneider's very fine and elegant analysis of liquidity preference and the investment multiplier.

The various techniques of banking policy—reserve requirements, open-market policy, discount policy, official declarations—are satisfactorily treated; but there is no discussion of objectives or guides of monetary policy. The best part of the chapter on Money and Banking is the exposition of the coefficient of multiple expansion of bank credit as a function not only of reserve requirements but also of differential habits of payments. This is a model of clarity.

Liquidity preference is Schneider's favorite theory. After having given it several pages in Volume II, he treats it again in the present volume extensively in connection with open-market policy (pp. 57-72), with the determination of investment and income (pp. 140-60) and with the refutation of the quantity theory (pp. 164-66). Since he admits that the significance of liquidity

preference is confined to short-run income analysis, one wonders why he accords it such generous treatment. The prominent rôle assigned to this tool of analysis is perhaps partly attributable to the fact that Schneider has developed an especially elegant way of dealing with it verbally, geometrically, and algebraically.

Mention should be made of the variant form of the liquidity function that Schneider uses to exhibit the relationships between interest rate, income level, and money supply by curves expressing the relationships between the first two of these variables with the third as parameter. These curves show the combinations of interest rates (determining the size of speculative cash balances) and income levels (determining the size of transactions cash balances) that can be accommodated by fixed quantities of money. Schneider, following Hicks, draws such curves with horizontal and vertical ends, indicating that the interest-elasticity is infinite at low interest rates (because of unlimited absorption of speculative cash) and zero at high income levels. This zero elasticity—since Schneider wants income to be understood as real income or money income with constant prices (p. 97)—must be due to a ceiling velocity of circulation preventing any higher income levels from being financed with a given quantity of money. Schneider, at one point, attributes these vertical ends of the interest-income curves to the fact that "with a given amount of money a definite money income cannot be exceeded, for reasons of liquidity preference alone. Higher incomes are possible only with a larger quantity of money" (p. 148). At another point, however, he attributes the vertical end of such an interest-income curve to "full employment" (p. 149); but the effects of full employment would be more correctly described by a family of these interest-income curves converging on a single vertical stretch, indicating the fact that no further increase in the quantity of money can succeed in promoting an income level beyond the full-employment level.

Schneider's exposition of pre-Keynesian, Keynesian, and post-Keynesian multiplier theory is the most useful part of the book. The quotations from N. Johannsen's early formulations of that theory, in 1903 and 1913, are very interesting. In the presentation of the Keynesian apparatus Schneider shows himself as one of the master-teachers of our time. I should like to point especially to the discussion of the savings function (p. 116) and of the interdependence of Keynes' (supposedly independent) fundamental functions (pp. 139-47). In presenting these relationships Schneider takes advantage of the ingenious methods developed (in Swedish) by Tord Palander.[1] It is made very clear why the Keynesian multiplier formula fits only a special case, namely, the very special assumptions that the interest-elasticity of investment is zero or the interest-elasticity of liquidity preference is infinite. A general multiplier formula is presented, containing terms taking account of income-induced changes of the interest rate and of interest-induced changes of investment (p. 151).

Schneider earns the characterization of his text as the most modern and up-

[1] T. Palander, "Keynes' almänna teori och dess tillämpning inom ränte-, multiplikator- och pristeorien." *Ekonomisk Tidskrift,* 44, 1942, pp. 233 ff.

to-date when he includes such recent discussions as Haavelmo's "multiplier effect of a balanced budget" (pp. 198-202) or Patinkin's, Hansen's, and others' views on the "Pigou effect" of continuing price reductions (pp. 158-61). But, as I said before, Schneider is modern also in the problems which he chooses to omit. This reviewer is particularly troubled by the fact that a three-volume text on economic theory, by an author who on many issues is an intellectual descendant of Wicksell, should be completely without any discussion of, or even reference to, capital theory. Of course, the pure theory of capital or of the time structure of production is relevant chiefly to a long-run analysis of income, and this the author has explicitly excluded from the scope of his book (pp. 93 and 178). But is there a good excuse for such an exclusion from a three-volume treatise on economic theory?

At one point of the present volume Schneider tries, as he has in the first volume, to contrast *ex ante* and *ex post* conceptions in economic analysis. This is what he says: "If we know the consumption planned by households for a future period . . . and the net investment planned by business firms . . . , then we are able to say what the resulting income will be if the plans of the households and firms are realized" (p. 93). How true and how useless! Yet, this statement is regrettably typical of much of our modern theorizing. Too often do we forget that one of the foremost tasks of economics is to explain and predict circumstances under which consumption and investment plans cannot be realized. And it is my conviction that capital theory is needed precisely for that task.

These remarks may seem to contradict my appraisal of Schneider's work as one of the most comprehensive of modern texts in economic theory. But there is no contradiction since capital theory is now generally out of fashion and its neglect is common to all modern texts. Thus my criticism is not directed against Schneider but rather against current fashion in economic theory. Indeed, I expect that most readers will side against the critic and with the writers who have expelled from economic theory the most complicated part of economics. This old-fashioned reviewer dares to predict that capital theory will be called back from its exile, for the concern with the economic problems of underdeveloped countries will eventually demonstrate that the lack of capital can neither be made good nor more palatable by a lack of capital theory.

FRITZ MACHLUP

The Johns Hopkins University

Economic Anthropology. By MELVILLE J. HERSKOVITS. (New York: Alfred A. Knopf. 1952. Pp. xiii, 547, xxiii. Text ed., $5.75.)

This book is a complete revision of the author's earlier work, which in the first edition (1940) was entitled *The Economic Life of Primitive Peoples.* Both the scope and analytical categories remain substantially the same. The principal changes consist of an introductory, theoretical chapter on "Economizing and Rational Behavior," a considerably expanded (though by no

means exhaustive) sampling of the relevant literature appearing within the intervening twelve years; expanded treatment of motivation and rewards for work (now two chapters instead of one); and a somewhat fuller treatment of the value concept and of the capitalization process in these societies. In this edition Herskovits also relates his general discussion and illustrative materials to a broader representation of economic theories.

As in the first edition, the "primary concern in these pages is to understand the cross-cultural implications of the process of economizing," with primary emphasis upon the "role of alternatives between which to choose . . . and the problem of attaining efficiency through choosing" (p. 4). Cultural factors, it is stressed, delimit not only the choosing but also the nature of wants themselves and the exchange system for the provision of goods and services.

It is apparent that, from the nature of the societies which he conventionally studies, the anthropologist finds the approach of institutional economists more congenial to his material. A perusal of the literature, for example, reveals the significance of gift and ceremonial exchange as the primary mechanism of circulating goods within a group. While the economic rôle of these processes can be readily traced in terms of magnitudes, frequency of occurrence, and personnel involved, the forces that determine their operation are mainly noneconomic: kinship, neighborliness, fear of sorcery, marital ties, etc. The concept of equilibrium, therefore, would have to be related not merely to the ratio of income to outgo in the society as a whole, but also to "motivation and the balance felt by the individual in his functioning capacity as a member of society" (p. 173).

Comparative study of economic behavior based upon peasant and primitive type societies poses certain difficulties for the economist, who might wish to draw upon a wider empirical base in support of his principles and propositions. Perhaps the foremost of these is the fact that such societies generally constitute small groups in which the intimacy of interpersonal relations is widespread. Kinship and familial reciprocities flavor all areas of activity. In addition to material inducements, incentives to work, for example, are caught up in varying patterns of mutual responsibilities based on these and related factors. Individuals discharge their responsibilities consistently as much in accordance with attitudes toward social (nonrational) as with those toward economic (rational) efficiency.

In the same way that the comparative analyses of cultures and societies by anthropologists contribute principally to sociological theories of small group behavior as compared with mass behavior, economic anthropology might be expected to contribute to middle-level hypotheses geared to the context of such groups. Propositions of this kind and the conceptual apparatus upon which they are based should be very useful for the empirical study of western economic behavior and institutions at the community level. Indeed it is only at the upper range of technological and societal complexity among folk-type societies that we encounter something like a classical economic system. Thus among the Panajachael of Guatemala we find local specialization in a competi-

tive market, buying and selling for cash, prices geared to supply and demand, with rates made on the basis of cost estimates (p. 235). Capital formation here as elsewhere, however, is minimal and does not occur in accordance with values of growth or progress.

The author has chosen to limit the parameters of his analysis so as to exclude the processes of change. This is perfectly permissible, but as he has adopted the title, *Economic Anthropology,* the reader might feel entitled to learn something from the considerable literature on changes in process among folk and primitive societies consequent upon the diffusion of Euro-American technology and socio-economic values. This omission is all the more lamentable in view of the extremely important increase in interest on the part of economists in theoretical problems of growth and development.

As a final comment, this reviewer would like to suggest as perhaps a more felicitous organizational framework for such a volume, a chapter or two pulling together theoretical considerations and problems discussed throughout, followed by a series of rather full case studies of nonwestern economic systems. The considerable range of variation among so-called primitive societies, as regards degrees of isolation, complexity, population size and density, makes this approach desirable, as well as more amenable to critical analysis by the student, than does the juxtaposition of isolated examples of bits of behavior in support of widely scattered general statements. There is presumably a high degree of interdependence of the parts of any such system. A good model for a brief introductory section as envisaged here is a splendid chapter by R. Firth on "The Social Framework of Economic Organization" in a recent volume entitled *Elements of Social Organization* (1951).

Like its predecessor the volume in review will be of primary value to the economist in demonstrating " . . . some of the discrepancies between [his] assumptions about non-pecuniary, non-machine economies and the actualities of primitive production, exchange and consumption."[1]

BERNARD J. SIEGEL

Stanford University

Economics: Trends and Issues—A Book of Readings. Edited by SCOTT KEYES. (New York: Russell F. Moore Co. 1952. Pp. ix, 508. Paper, $2.90.)

The present collection of article reprints, intended as supplementary reading for the beginning student, enters its struggle for market survival in competition with recent collections by Gayer, Harriss, and Spencer (1951); Hess, Gallman, Rice, and Stern (1951); Isaacs, McKee, and Slesinger (1952); and Samuelson, Bishop, and Coleman (1952)—among others. It is a rare anthology that pleases all, and there is always the temptation (in the absence of some solicitous publisher who would issue separately bound individual articles) for each economics department to compile its own "best" offering.

[1] From a review of the first edition by C. M. Arensberg, *Am. Econ. Rev.*, Sept., 1940, XXX, 595.

Keyes's book contains an impressive list of contemporary contributors, drawn with few exceptions from the ranks of professional economists. The articles give a beginning student an excellent sampling of many current economic problems and the techniques used by those working on them.

Part I is the usual sort of introductory section on the scope, method, and need for economics. Aside from an informative excerpt from the 1949 Report of the Council of Economic Advisers, there is an unusually well-written and appealing lead article entitled "It's Political (Repeat Political) Economy." The book's long second part is an exposition of "Basic Characteristics of the American Economy," and features such authorities as A. A. Berle on industrial concentration, Hauser on Census trends, and Leontief on the cost-price structure. Methods of economic measurement are explored further in the third section, with Commissioner Clague holding forth on the Bureau of Labor Statistics Consumers' Price Index, and Richard Ruggles contributing a most useful chapter on national income accounting in relation to policy decision-making.

Part IV covers Keynesian economics and the sort of model-building and forecasting attempts to which it has given rise. Gerhard Colm discusses the Nation's Economic Budget, and there are illustrations of the current investigations by the Survey Research Center and by the Department of Commerce into determinants of consumer and investor behavior. Various policy problems are considered at some length in Part V, with the authors ranging from the members of a recent American Economic Association subcommittee on economic instability to Paul Douglas on the welfare state and Gordon Gray on foreign economic policy. A final section presents, all too briefly, a potpourri of J. M. Clark, Polanyi, and Schumpeter on economic thought, economic development, and comparative systems. The section concludes with the United Nations comparison of seventy countries' national and per capita incomes which, even after severe statistical qualification, retains a powerful impact.

In his preface, the author claims four major virtues for his book as compared with similar compilations. First, all the articles included date from the post-World War II period, with many only a year or two old. This immediacy of the writings may well give students an "up-to-date" view of economic problems and policies, but if not offset by classroom references to earlier works might equally well lead to an impression that all worth-while thoughts in our venerable science have been uttered only in the last few years. Those teachers, therefore, who desire to instill some acquaintance also with earlier giants of the field will not consider this distinctive feature an unmixed blessing.

A second distinguishing characteristic, suggested earlier, is that all the selections are from professional (including governmental) sources. This approach has resulted in a consistently high caliber of performance which ought to please economists. But again one might question why students should not also have been exposed to some other sources, ranging from Marxist tracts to National Association of Manufacturers releases, such as they may or should debate in their own everyday lives. The third point, that almost all the articles are presented in uncut form, does seem an undeniable virtue. About half the

thirty-five articles (far fewer than in other compilations) run from 10 to 15 pages, avoiding the usual pitfalls of excessive length or fragmentation.

Finally, the material has been selected with especial emphasis on means of measuring, and actual appraisals of, the changing developments of the past two decades. This approach produces a slighting of relative-price and allocation problems to a degree probably greater than is merited. In this sense the volume would serve more usefully as a supplement to introductory courses in income and employment than to those in price theory.

On the whole, though, it seems a virtue of this work in comparison with others of its sort that it does not dilute its coverage in an attempt to be all things to all courses. While the need for books which link beginning students with contemporary problems is even more pressing (because more difficult) in the fields of price, allocation, and market theory, within the scope he sets for himself Professor Keyes has given us a most useful educational tool.

The School of Salamanca: Readings in Spanish Monetary Theory, 1544-1605. By Marjorie Grice-Hutchinson. (New York: Oxford University Press. 1952. Pp. xii, 134. $2.50.)

The author of this little volume holds that Spanish writers have a claim to recognition in the development of economic thought which has been overlooked. She believes that this is especially true of the sixteenth and seventeenth century scholars identified with the University of Salamanca. In her appraisal of this group, Professor Grice-Hutchinson concludes that they made original and useful contributions in three important respects: a psychological theory of value applied to both goods and money, the quantity theory of money, and a theory of foreign exchange closely resembling the modern purchasing-power parity theory (pp. 47-48, 58).

The translations from original texts confirm her thesis that members of the School developed their idea of value around the concept of scarcity and utility (pp. 48, 36). Domingo de Soto set the pace when he declared that "the price of goods is not determined by the wish or convenience of individuals, but by the community," and added "that is by common estimation" (p. 83). He concluded that "prices rise when buyers are numerous and fall when they are scarce. Likewise, prices fall when sellers are numerous and rise when they are scarce" (p. 86). In a carefully documented chapter the author traces the influence of the Spanish writers through Grotius, Pufendorf, and Hutcheson, but fails to connect the statements on utility and rarity of Galiani, Condillac, and Turgot with the Spanish writers.

In the opening chapter, the author says, "the whole Spanish nation had learned by the middle of the sixteenth century that the value of money is fickle and that gold and silver are not synonymous with wealth" (p. 1). She contends that prices rose first in Spain, and that Spanish writers were first to note and trace the causes of the price revolution. Martin de Azpilcuetta

Navarro noted the influence of gold and silver on prices in Spain and applied the theory of demand and supply to money. His exact statement is, "And even in Spain, in times when money was scarcer, saleable goods and labor were given for very much less than after the discovery of the Indies, which flooded the country with gold and silver. The reason for this is that money is worth more where and when it is scarce than where and when it is abundant" (p. 95). Tomás de Mercado, however, seems to have the typical mercantilistic outlook (p. 96). In view of the mercantilistic legislation in Spain and the prevalence of mercantilistic tracts cited by Earl J. Hamilton in his studies of Spanish prices and Spanish mercantilism, some question remains as to how well the Spanish had learned the lesson.

Professor Grice-Hutchinson asserts that Navarro was the first writer to mention the influence of the imports of American gold and silver on Spanish prices and that his analysis of the quantity theory of money anticipated Bodin by twelve years. A comparison of the two writers reveals that Bodin was more thorough and there is little doubt that it was through the work of Bodin that the concept entered the field of economic literature.

The most original contribution of the School of Salamanca centered around their explanation of the variation of the exchanges. Here they definitely connected the price levels of the countries with favorable or unfavorable rates of exchange. While their version of the purchasing power parity was interesting and useful in relation to the question of exchanges and usury, any direct influence on later advocates of this theory came through Malynes and Mun rather than the Spanish writers

In providing an English translation of these early Spanish tracts on monetary thinking, Professor Grice-Hutchinson has filled a gap in this chapter of the history of economic thought. Teachers and students will welcome her careful and lucid appraisals of the School as well as the availability of the original texts.

RECTOR R. HARDIN

University of Georgia

The Development of Economic Thought. Edited by HENRY WILLIAM SPIEGEL. (New York: John Wiley & Sons. London: Chapman & Hall Ltd. 1952. Pp. xii, 811. $6.50.)

The history of economic thought abounds in good texts, long and short, analytical and descriptive, topical and chronological. There are also useful books of readings, masterworks, and compilations of short selections from the important writings of great economists. The volume under review is distinctly different. It is a history of economic criticism in the form of a collection of appraisals of the contributions of outstanding economists by later economists. In short, the book contains many of the best statements about the most important figures in the history of economic thought.

This volume by Professor Spiegel, therefore, supplements both texts and readings in its field by providing additional material of high quality in acces-

sible form. It gives the student better perspective by substituting the varied viewpoints of many observers for that of one scholar. It permits him to see how important economists have been regarded by different competent critics, and to discover how well they have met the issues of their day and have stood the test of time. The "craftsmanship" approach to this history of economic criticism is as unique as it is valuable and stimulating.

The book, consequently, should become popular in courses in the history of economic thought. Brief, helpful editorial notes introduce the various selections, some of which are familiar classics but others of which are new translations by the author of less familiar articles. The volume has a succinct foreword by Kenneth Boulding; there is also an explanatory preface by the editor. The index seems adequate. As will be shown, the coverage of the book is wide, and its organization is excellent.

The Dawn of Economic Science (the first part) gives Aristotle on Plato, Tawney on medieval economic thought, Heckscher on Mercantilism, Jevons on Cantillon, Smith on the Physiocrats, and Spiegel's own translations of Einaudi on Galiani and of Marx on the Physiocrats.

The Classical School (the second part) contains the article by Paul Douglas on Smith, those by Bonar, Fay and Keynes on Malthus, by McCulloch and Marshall on Ricardo, that by Mill on Bentham, by Viner on Bentham and Mill, by Cairnes on Bastiat, and by List on Say.

Socialists and Reformers (the third part) is rather short and seems insufficient. It includes articles by Halévy on Sismondi (editor's translation), Foxwell on Ricardian Socialists, Cole on Owen, Veblen on Marx, Hobson on George, and Tawney on the Webbs.

Historical and Institutional Approaches (the fourth part) is short but adequate. It contains Schmoller on Roscher (editor's translation), Mitchell on Veblen, Perlman on Commons, and Arthur F. Burns on Mitchell.

The Rise of Marginalism (the fifth part) is longer and even more valuable. It contains articles by Schneider on Thünen, Fisher on Cournot, Walras on Gossen (editor's translation), Keynes on Jevons, Hayek on Menger and Wiesser (editor's translation), Schumpeter on Böhm-Bawerk (editor's translation), Hicks on Walras, and J. M. Clark on J. B. Clark (previously unpublished article).

The Growth of Modern Economics (the sixth and final part) is short but helpful; it is naturally the most controversial as to what to include and what to exclude. It contains articles by Arthur L. Bowley on Edgeworth, Demaria on Pareto (editor's translation), Frisch on Wicksell (new article), Robbins on Wicksteed, Viner on Marshall, Haberler on Schumpeter, Samuelson on Keynes, and Colin Clark on Pigou (previously unpublished article).

The reviewer has little fault to find with what has been included in this collection of criticisms in the history of economic thought. His chief lament is the omission of important writers and entire schools of thought. The omitted schools include the Idealists or Moralists (except for Halévy on Sismondi and Hobson on George). With regard to individual writers, a few pages might well have been given to Marion Bowley on Nassau Senior. The obvious answer to

the criticism that whole schools of thought have been omitted is, of course, the limitations of space. Also, time has dimmed the importance of such once-famous optimists as Carey and his followers, even in America.

S. HOWARD PATTERSON

University of Pennsylvania

Economic History; National Economies; Economic Development

Trade and Industry in the Middle Ages. Edited by M. POSTAN and E. E. RICH. Cambridge Economic History of Europe, Vol. II. (New York; Cambridge University Press. 1952. Pp. xvi, 604. $9.00.)

Volume I of this series, published in 1941 and dealing with medieval agrarian life, announced in its preface that Volume II would be "urban, industrial and commercial." The general design was for an economic history of Europe, "or of the world as it impinges on Europe," starting formally from the later centuries of the Roman Empire. War and its aftermath removed contributors and cut off areas beyond any normal expectations. The schism of Europe concentrated upon the western part an emphasis which was planned for the whole continent and is particularly unfortunate for a discussion of industry and trade. Urban problems, defined as the growth, economic policies and finances of towns, together with "the history and policy of craft gilds" are now put over to Volume III, already slated to deal with medieval credit, finance, coinage, prices, state economy and economic thought.

In thus modifying a plan which had the advantage of corresponding roughly with university syllabuses, textbooks and the specialization of research, the new editors state that the earlier plan would have overloaded the second volume and was no more logical than the substitute. They admit that "background" topics such as prices, population and economic trends should be incorporated, not put off to the final volume on the medieval period. What this chiefly means in practice is their inclusion in Postan's tremendous (132 pages) chapter on medieval North-European trade. The reviewer wonders if this was the reason for placing his chapter before Lopez's chapter on medieval South-European trade. Considering his position in the craft, the rounded statement of Postman's interpretation may well compensate for more detailed chapters unavoidably lost.

However, a volume which is even more west-European in outlook than the first makes a notable concession with respect to the temporal starting point. An opening chapter by Gordon Childe discusses the industry and trade of "barbarian Europe" through stone, bronze and two iron "stages," down to Roman times. Like Heichelheim years ago, he sketches the distribution over great distances of products of basic industry—such as flint and obsidian points and edges—before written records. He also stresses the importance for economic development of trade in ornaments and other luxuries. This position seems difficult to harmonize with Postan's.

Chapters on Rome and Byzantium by Wilbank and Runciman are inter-

esting and informing, but seem to the reviewer too specific for a work of general synthesis. There is little to suggest the perennial movements out of Asia or a westward movement of settled life along both sides of the Mediterranean which was far from complete when the Roman Empire in the West broke up. That the Romans occupied only about half of the Atlas highland region of Africa and little of the Sahara is a fact with large reverberations in medieval and modern history. The way in which the Moslems completed the occupation, trade relationships between Spain and Africa during the great development of Moorish intensive agriculture, and the whole problem of Africa as a "granary" of Europe from Caesar Augustus to Lebrun and Daladier have surely "impinged" upon Europe more than incidentally.

The figure of 10,000,000 bushels for Rome's grain imports from Africa (p. 47) rests on no substantial evidence, and tends to distort the problems of population and food supply. Victor Demontès arrived at it in 1925, Tenney Frank in 1940, by putting together casual statements of Flavius Josephus and Aurelius Victor, made three centuries apart. Frank seems to have been aware that it is absurdly large for the number of mouths. Close students of the African area (roughly present-day Tunisia and the Department of Constantine) are roughly agreed nowadays on a maximum of some 3,000,000 bushels, and accompany any such figure with the warning that most crops in this erratic climate must have afforded less, some no exportable surplus at all.

One gets the impression of a more populous Roman Gaul from this volume than from the first. A treatment of thinly documented commerce over a long period has an almost unavoidable tendency to yield an exaggerated picture. Statements of absolute quantities in discussing earlier societies have the opposite tendency, whether comparisons with our time are made or left to the reader. Several of these authors quite properly insist that the volume of trade is a function of a particular society and situation, and is best not mentioned out of its setting.

Postan discusses the problems of quantities and records of quantities in medieval North-European trade after noting the character of the commodities exchanged and their approximate order of importance. His emphasis on interregional trade in staples is no greater than, for example, Rörig's in his 1933 *Mittelalterliche Weltwirtschaft*, but Postan's argument has another facet. Insistence upon the predominantly staple character of trade within medieval northern or transalpine Europe is made to suggest the relative independence or separate development of the area, and hence by implication to combat any notion of a dominance-and-dependency relationship with the Mediterranean. Rörig, and back of him others including Sieveking and Davidsohn, have noted the importance of staple foodstuffs, textiles, raw materials and other nonluxury items in Mediterranean trade, as does Lopez in this volume. Moreover, as Schulte, Rörig, Braudel and others have explained, staples were fairly important in the interregional trade between the Mediterranean and the North. Finally, as the various societies were organized, trade in luxuries was not necessarily unimportant or even indecisive for development, as Childe has noted in this volume. Consistently with his position on staples, Postan is

allergic to explanations of development as responding to changes in the supply of monetary metals or in prices. He is careful (*e.g.*, p. 166) to note that he is not arguing against such explanations as applied to later centuries. Like Rörig and others, including Usher, he stresses the importance of frontiers in medieval economic development, and notes that Hanseatic trade was roughly at its peak when the League was founded.

The main innovation in Postan's version of Hanseatic policy as defensive rather than progressive is his correlation of German history with a long and general contraction or depression which scholars have stressed in varying degrees of late years. Roughly speaking, the Black Death of about 1347-1350 marks the onset of this period, though recurrent epidemics, the Hundred Years' War and other struggles of the time figure prominently in the asserted decline. Note that the Hanseatic League is dated roughly from the 1360's. Postan argues that Europe's population, cultivated area, production in general and trade all declined for something like a century, following a much longer period of growth. The prevalence of strong sentences about decay and weak sentences about growth in this immense and generally moving argument made at least one reader slightly uneasy.

Lopez has a much more restricted and moderate version of this interminable depression in discussing the Mediterranean area. Nef, in a chapter on mining and metallurgy which has a remarkably sustained continuity, would settle for about the same population in 1350 and in 1450. It may be recalled that Josiah Cox Russell (*Speculum*, 1945) believed in a decline of population from about 1348 to 1430, the latter time roughly marking a turning point. He relied mainly on demographic statistics. Postan presents a great variety of evidence, which is quite proper, but the reviewer got an impression that the meager population figures tended to disappear in the mixture. Consistent with its presentation of development in northern Europe as roughly equal and step by step with that in the Mediterranean region, Postan's chapter seeks to rescue medieval England within northern Europe from the relatively backward position which it has occupied in general accounts. This volume has no continental authors, as compared with twelve in the first.

In the other nuclear chapter, dealing with medieval trade in the South, Lopez has taken over less of the general subject-matter left homeless by failures of expected contributions to materialize. Considering his learning and his many revisionist studies, he here displays notable restraint, often retreating to sample cases on the ground that wider generalizations would be unsafe. Among the many revisions in this chapter, perhaps the most startling is that the fourth crusade was not diverted to Constantinople, but was so planned from the outset (p. 311, n.). The opening of the Black Sea to Latin traders was significant, but the crusade as such was a failure because Asia Minor was not taken. Two attempts to make Damietta in the Nile delta a Latin bridgehead failed, and the evacuation of the Holy Land for trading outposts on Cyprus and in Cilician Armenia was only a question of time. The only real disaster for the West resulted from a Papal ban on trade with Egypt, which the Catalans ignored, probably harming Venice and Genoa more than they helped themselves. Italian

business organization at the zenith of commerce and capitalism (his terminology), from the late 11th to the early 14th century, is discussed with tantalizing brevity. The great Italian diaspora by sea and land is placed in its historical setting. Having objected on page 338 to Pirenne's term "saturation" to characterize the crisis beginning around 1350, Lopez proceeds on page 344 to state almost exactly what people using the term have meant by it: in this case the end of frontiers and the tribulations of business organized on the assumption of continuing expansion but facing the reality of too many competitors for available markets. Like other authors of this volume, he thus explains a tendency toward defensive and regulative organization.

One slightly confusing feature of this volume is the variety of "middle ages." To Lopez, the period ends with the fall of Constantinople and the end of the Hundred Years' War in 1453. Postan generally carries it to about 1500. One of Nef's ten subdivisions is entitled "The Boom in Mining and Metallurgy, 1460-1530." Nef's chapter is itself a gold mine and hard to sample. The Romans, often accused of being unoriginal as engineers, are exonerated. They had quite deep mine shafts, as much as 600 feet, and their mechanical equipment as well as their processes were more advanced than any afterward to the 14th century. Nef makes one of the most interesting comments—amounting to a "saturation" theory—on the "great depression" of the latter middle ages. A tremendous and sustained medieval extension of settlement opened vast mineral deposits near the surface. Uses multiplied. In the end, shallow deposits began playing out much more rapidly than methods and equipment for deeper mining were developed. Nef's discussion of the generally free status of medieval miners, as compared with slavery and low esteem in ancient times, is most interesting. Another subject which he divests of countless illusions is that of regalian subsurface rights.

But the most informing chapter on medieval human relationships within a profession is that of Jones on building in stone. Somewhat like the merchant trading at a distance, the master or other mason typically operated largely outside his home area. Hence he was unusually free from local regulations. The prevalence of wages, and of even quite large-scale contracting, have been recognized especially since the author and Mrs. Knoop published their 1933 study on the economic history of English stone building in late medieval and early modern times. This work got long and enthusiastic reviews on the Continent. Jointly and individually, its authors have written much on the subject, but nothing which quite renders the service of this relatively brief synthesis.

Chapter 6, by Eleanora Carus-Wilson, on the woolen industry from the Romans to the triumph of English cloth is an illuminating discussion of a key subject. In the area around Flanders, the industry took hold because of the excellent wool and the situation for trade. Soon it outgrew the local supply of wool. English wool was the best, but there were competitors for it, clothiers in England itself eventually taking the major part and with it the market for cloth. Everywhere there was some danger that mere craftsmen would become organized, force participation in public affairs, and perhaps even get control of city governments. Only in Flanders did this occur on a large scale, and it

occurred at a time when the goose that laid the golden eggs was itself struggling for survival. The author has stuck closer to woolens than Rörig did to fustians, in an account which is vastly broader in effect than one industry together with the trade in its raw materials and product.

The extent and quality of the revisions presumably measure the importance of a volume such as this, consisting of syntheses by ranking experts. This book is well written, but not for babes—it is highly condensed and presupposes either some knowledge of history and geography or access to reference works. The advanced students, including teachers, to whom it is addressed first of all, will disagree with some judgments expressed. The reviewer thinks that some distortion has resulted from placing the chapter on northern Europe before that on southern Europe. Some factual statements may be questioned—not very many, I think, for it is competent work. The volume will be read, and will influence beliefs and interpretations, for many years. This is my excuse for writing so many words about it, knowing full well that it must be read in order to gain any sound appreciation of it.

The Browns of Providence Plantations: Colonial Years. By James B. Hedges. (Cambridge: Harvard University Press. 1952. Pp. xviii, 379. $6.00.)

This book, the first of a projected three-volume history of the family, carries the story of the Browns of Providence Plantations from the date of the first ledger entry by Captain James Brown on October 9, 1723, down to the ratification of the federal constitution by Rhode Island in 1790. In tracing the business activities of the family through these years, the author has drawn upon an unusually complete collection of letters, journals, receipts, invoices, and contracts. The result is a significant contribution to our understanding of the colonial business man; one that compares favorably with William T. Baxter's study of *The House of Hancock* or V. D. Harrington's book on *The New York Merchant on the Eve of the Revolution.*

Like most of their contemporaries among the colonial merchants, the Browns were ready to consider almost any venture that gave promise of financial reward. This led them to engage in such diverse activities as trading along the Atlantic and Gulf coasts and with the West Indies, hauling slaves from Africa, writing marine insurance, trading with England, sending out whaling expeditions, trafficking with the enemy, blockade running, and privateering. But the Browns were more than merchant shipowners. They started grinding cocoa beans as early as 1752, their spermaceti candle works were in operation in 1753, and in 1755, they took the first steps leading to the construction of an iron manufactory that began turning out pig iron and hollow ware a year later. In fact, by 1765, ". . . the Browns had become manufacturers first and merchants second. When capital was available for business expansion, it went not into a larger merchant fleet but into another branch of manufacturing" (p. 123).

These various activities are described in considerable detail and much new information is made available, especially in the chapters on the manufacture and distribution of candles and iron products. The author brings out very clearly how the diverse parts of the business were all integrated into a well functioning administrative unit. Multiple operations were in themselves insurance against risks that attended almost every phase of operations. The Browns were skillful in adapting their business to circumstances that changed frequently and sometimes violently.

According to the author, the members of the family were not endowed with any uncanny ability to foresee the future turn of events. "The secret of their long-sustained success lay primarily in the personal qualities and business methods of the family" (p. 329). Careful planning went into providing leadership from one generation to the next. "A younger brother, a son, or a nephew well trained by his elders was always ready to assume the responsibilities of leadership at the proper time" (p. 329). Interest in perpetuating a family business prompted a subordination of short-term profits to a long-run view of operations. No important move was undertaken without careful planning, be it a project to corner the tobacco supply for shipment to Surinam, or a decision to equip a privateer. These same considerations apparently account for the fact that the Browns were seldom innovators in the strict meaning of the term. Obadiah Brown in 1736 was the first Providence merchant to engage in the slave trade, but this was long after the Newport captains had shown the way. The Browns were not the first to manufacture spermaceti candles in the new world and they drew heavily on the experience of Pennsylvania iron producers in the construction and operation of their own furnace.

These points are well made and emerge logically from the more detailed accounts of the business. There are, even so, some aspects of the family's policies and practices that are not entirely clear. Why, for example, did the Browns trade with the Dutch rather than the British West Indies? Why were their first connections in England with merchants in Liverpool and Bristol and not London? Was this, as one reviewer has suggested, because the Browns did not belong to the elite class of colonial merchants, came from Providence and not from New Port or Boston, and lacked proper social and governmental connections?[1] Would missing records or a closer examination of existing documents give a clearer picture of the business arrangements within the family and with outsiders on particular ventures? Is the impression gathered from the narrative correct, that at no time after 1723 was the raising of capital funds a limiting factor on expanding operations? Could such funds always be provided from within the business or when the Browns joined with others on particular projects was it to obtain financial support and not simply a measure designed to distribute risks?

But the raising of these questions is more of a tribute than a criticism of a study that by its excellence makes us eager for others of equal quality.

Studies in British Financial Policy, 1914-25. By E. VICTOR MORGAN. (New York and London: Macmillan. 1952. Pp. xii, 380. $6.50.)

Of interest primarily to the specialist in British finance, these studies are also of interest to the general student of "defense economics." They tell the much-told tale of the great changes that came over the British financial economy from the outbreak of World War I to the return to gold in 1925, but tell it with the help of previously unavailable data and the better analytical tools that are a legacy of the "Keynesian revolution."

The book is divided into four parts. Part I, "Preliminaries," describes the financial crisis following the outbreak of war and the emergency measures taken to combat it; the growth and abandonment of "direct" wartime controls; and general movements of economic activity over the entire period. Part II, "Government Finance," deals with expenditure, revenue, borrowing and conversion operations, the changing structure and distribution of the national debt, and movements of interest rates. Part III, "Money, Credit and Prices," describes the wartime currency arrangements, and the activities of the Bank of England, the money market firms, and the joint-stock banks. The chapter describing price movements includes a useful analysis of the "mechanism of price changes" along modified Keynesian lines. Part IV, "External Problems," analyzes the balance of payments on current and capital account, external wartime borrowing and lending, and exchange rates. A concluding chapter summarizes the findings of the studies as a whole.

The presentation and derivation of statistical series and estimates occupy a very large number of pages. Only the hardy explorer of the jungle that is British financial statistics will find these fascinating. One can only see the importance of the book by reference to its final chapter. Yet there, as well as tucked in among the statistics, are judicious criticisms of financial policy and generally well-balanced judgments of the importance of various causal factors in the inflation, the deflation, and the mid-'twenties slump.

The author's main conclusions can be briefly summarized. "Budgetary policy was the major cause of the steep price rise of 1915-17 and of the controlled inflation which continued during the closing phases of the war." (It is evidence of the progress made in the theory of wartime finance that only a generation ago the British government thought it "sound" wartime finance to impose new taxation only sufficient to meet the rising interest charges and a sinking fund on the increased national debt.) Fiscal policy is seen as an *active* inflationary force only up to mid-1917, however; thereafter "the deficit played the role not of creating new demand, but of sustaining the Government's existing purchases in the face of rising costs." During this latter period Morgan considers the main weakness to have been uncontrolled wages.

Monetary policy, while fumbling, is seen as only a minor villain in the wartime inflation. "It is one of the main theses of these studies that money and credit exercised a permissive rather than a causal influence." The Bank of England was hampered in its monetary control by an influx of gold and "automatic" issue of currency notes and Ways and Means Advances to the Treasury. But, in the main, technical devices and Bank-Treasury co-operation overcame

these difficulties. There is no suggestion that monetary policy could have done much more to prevent inflation.

In the brief postwar boom, Morgan finds, "Government finance . . . ceased to have any directly inflationary effect." Direct controls were relaxed too soon. Interest rates, though very high, were perhaps not raised high soon enough. But the boom was mainly brought about by rising consumption expenditures, a burst of private investment, and a sharp change to a large favorable balance on current international account, conditions largely beyond practical control by monetary policy.

Morgan criticizes most severely the handling of the slump of 1920-21, and the semislump of 1922-25. Substantial budgetary surpluses aggravated the malady, as did the maintenance of high Bank and market interest rates in 1920-21. "The extreme eagerness" to reduce the short-term debt by funding operations, an attitude based on "a widespread misunderstanding of the dangers associated with the floating debt" was especially injurious. "Once the boom had broken, spending required not restraint but stimulus." A more liquid debt structure and further broadening of the cash base "would have done nothing but good."

Morgan finds little evidence, on the other hand, for the view that monetary policies aimed at a return to gold at prewar parity were a serious depressing influence in 1924-25. "Both deposits and advances were maintained at high levels and short-term rates were moderate, while the fact that long-term rates were higher than before the war was due to conversion operations rather than banking policy." Here, it seems, Morgan has failed to give proper emphasis to the *trade* disturbances caused by the rise of sterling. He rightly points out that the wartime destruction of Britain's short-term creditor position, and the worsening of her general trade position, were serious difficulties regardless of the level of sterling. But this further impairment of Britain's competitive position, plus the greater measure of domestic monetary and fiscal austerity required to achieve and maintain prewar sterling parity, certainly aggravated these difficulties.

Morgan's gifts to the statistical jungle-fighter are substantial. He has obtained from the Treasury and the Bank of England hitherto missing data on such important matters as: the operations of the "British Treasury Account in New York" (through which was channeled a large part of Britain's external war finance); British wartime loan transactions with belligerents and neutrals; and wartime gold production and management. These hitherto secretive institutions also provided Morgan with numerous pieces of technical information bearing on their domestic operations during the war. (Still kept secret, interestingly enough, are such "vital" statistics as the nature of the securities held in the wartime "Currency Notes Redemption Account," a complete breakdown of "Government" and "Other" securities held by the Bank of England, and the amounts of wartime "Special Deposits" with the Bank.)

On the basis of these new data, plus judicious use of published statistics and earlier studies, Morgan makes many improved estimates. Such include: *internal* wartime government expenditures and revenue; the impact of the war on the

distribution of holdings of the national debt; a complete wartime balance of payments on current *and* capital account; and the wartime deterioration of Britain's net short and long-term creditor position. Morgan's work will be a valuable source book for close students of British financial history.

JAMES S. EARLEY

University of Wisconsin

Economic Forces in American History. By GEORGE SOULE. (New York: William Sloane Associates. 1952. Pp. viii, 568. $4.75.)

The structure of George Soule's economic history of the United States is unusual. The first 218 pages (Part I) relate to developments prior to 1900, while a larger portion of the text, the next 313 pages (Part II), covers merely the first half of the twentieth century. The emphasis on recent history is explained by the author as the result of an endeavor to illuminate the current scene, which exhibits a much greater complexity of the economic process than do the earlier years. The first part of the book begins with a brief chronology of events up to 1900. This is followed by a statement of seven themes for the period and an equal number of chapters—one dealing with each theme and each introduced by a short summary. In Part II the order of presentation is reversed: seven chapters dealing with particular topics are followed by a four-chapter chronological coverage of the post-1900 period.

To present a detailed discussion of the most important topics and at the same time to make the reader conscious of the broad aspects of development is the most difficult task of the historian. Each section of Soule's book, whether it is a discussion of one topic over time or a general chronology of events, provides a good description supplemented by an adequate amount of what might be called "short-run" analysis. The book is essentially a collection of very good essays, which are not effectively tied together—as far as this reader is concerned—despite the author's use of chronologies.

The failure to give the reader a feeling of economic development is a serious defect and has a two-fold basis. Part II is quite independent of Part I; it is as if the post-1900 events had no relation to those that preceded. Secondly, the author neglects to stress the broad underlying forces that account for general developments. His explanations of developments are in terms of short-run phenomena. A prosperous period, for example, is explained in terms of what has taken place in the immediate past (or takes place as prosperity grows) in agriculture, in certain specified manufacturing industries, etc. But, except for a chapter dealing with technology, no more than passing references are made to long-run forces of development. No stress is laid on the widening of the market for goods that occurred as a result of railroad expansion, and no connection is built between the widened market and a number of phenomena of the late 19th and early 20th centuries: the "trust" problem, the labor problem, various problems of urban growth, and so forth. Concerning the automobile, it is just as necessary, it seems to me, to write in terms of the wider market it has given labor and the numerous long-run repercussions of such a

widened market, as it is to write in terms of the changes in the demand for (and supply of) automobiles and the repercussions of these changes on a phase of a given business cycle. The latter Soule does well; the former gets no attention. Such omissions give the book a lack of unity that evolutionary threads would provide.

In many ways the presentation is very good. After the reader gets over the first few pages of "fine" phrases, the separate chapters will appear as excellent essays. This is particularly true of the chapters of Part II where the author treats technology and the volume of production, various aspects of national income, the rôle of money, international economics, the labor force, the ups and downs of the farmers, the relations between government and business, and the events of the last fifty years in a well-organized running account. Some readers may object to the favorable attitude toward the increasing rôle of government in the economy, but only ardent opponents of intervention will be offended. The short-run forces are very well handled, but the scant treatment of the long-run, basic, fundamental forces is disappointing in a book entitled *Economic Forces in American History*.

G. HEBERTON EVANS, JR.

The Johns Hopkins University

Report on Cuba. Report of a Mission of the International Bank for Reconstruction and Development. (Washington: International Bank for Reconstruction and Development. 1951. Pp. xxiv, 1,049. $7.50.)

This book, the work of sixteen authors who comprised an International Bank Special Mission under Francis A. Truslow, is a virtual encyclopedia on the economy of Cuba. There are chapters on topics ranging from Mineral Resources to A Bag Mill for Cuba. The first two chapters present the diagnosis and recommendations, while the remaining 48 chapters cover specific problem-areas that are relevant to an analysis of the development task in which Cuba is engaged. The book abounds with descriptive material of significant reference value.

As would be expected, sugar is the target of extensive critical analysis. The dominant theme is that too large a part of Cuba's total economic effort is in sugar and not enough in a diversified list of other products. Sugar is a seasonal industry, offering employment mainly over a period of four months beginning in the middle of winter. Moreover, the product is subject to the vagaries of price fluctuations traceable to Cuba's rôle as a residual supplier in the world market. By diversifying its output, Cuba could make more effective use of labor resources, reduce the impact of varying prices and export outlets for sugar, and perhaps moderate the disincentives of the unenterprising gambling spirit that is said to be a by-product of heavy reliance on the changing fortunes of sugar.

A variation on the main theme is labor policy, particularly the high wage demands and featherbedding that characterize contemporary Cuban labor. Such labor demands and practices, we are repeatedly told, constitute a stum-

bling block to industrial and agricultural diversification that is only second in importance to the national habit of pinning hopes on sugar. If there is anything to the idea that wage levels are established in export industries, however, it seems to me that the complaints of Cuban development enthusiasts and the Mission really demonstrate the strength of sugar's comparative advantage rather than many of the things mentioned in this *Report*.

Another point that recurs throughout the volume is the reluctance of Cubans to invest their savings in ways that accelerate the economic diversification of the economy. There is too much investment in real estate and American securities, and too great a propensity to hold idle balances. But are rates of return, the necessary allowances being made for special (and very great) risk factors, really more attractive in many of the lines that accord with the diversification thesis? Since there is little in the *Report* to indicate that the motivation of Cuban investors is significantly different from that of our own people, one wonders whether anything like the appropriate allowance for risk is made by those who are critical of Cuban investors. In fairness, however, it should be pointed out that the Mission calls attention to the need to improve the investment climate in Cuba. If this is done, and it can only be done by the Cubans, perhaps the resulting pattern of investment in due course will yield the much-desired returns in terms of a solidly based diversification of the economy. Domestic (gross) savings, incidentally, averaged about 13 per cent of Gross National Product during 1945-49 (p. 516)—a fairly respectable figure, even after allowance is made for the favorable position of sugar at the time. Although such an investment climate would do much to facilitate augmented foreign investment in the country, the *Report* is strangely silent about this aspect of the development problem.

Mention may also be made of several of the more important general recommendations of the *Report*. It calls for a re-examination of Cuban-American tariff preferences, urges that steps be taken (despite the restrictions of bilateralism) to expand the sale of sugar in Europe, recommends (with praiseworthy emphasis) against the establishment of a stee industry in the light of resource deficiencies, market size, and economic proximity to the United States, advises that policies should continue to stress the value of exchange-rate stability without exchange control, and recommends that monetary and fiscal measures which aim at general economic stability be restricted to those that are consistent with exchange-rate stability.

One misses a general statement of the theory of economic development, especially in its application to Cuba, a country that is among the most developed of the underdeveloped areas. If a chapter or two had been devoted to such a theoretical statement, readers would have been able to obtain a clearer idea of the Mission's conception of the development problem. We are all for economic progress in the form of rising per capita production, especially when it is not entirely or mainly at the expense of others than the nationals benefiting therefrom. In particular, such a theoretical statement would have been helpful by setting forth the chief assumptions involved. Moreover, I venture to assert that if a careful theoretical statement of about 5 per cent of the size

of the volume had been written, much of the descriptive material would have told a more persuasive story, the alternative opportunities for using labor during the "dead season" in sugar production would have been stated more effectively, the length of the *Report* considerably shortened and repetitive material omitted, and the necessarily slow process of development more clearly demonstrated. The last point in particular deserves emphasis. Strong emphasis on the process of development would have integrated the various parts of the *Report* and indicated in a more logical way the responsibilities of individuals, firms and government if given objectives are to be met. There is every reason to believe, however, that the volume should have more than a modest guidance value to the leaders of the Cuban community upon whom, in the last analysis, the task of development falls.

VIRGIL SALERA

Washington, D.C.

The Economic Development of Guatemala. Report of a Mission sponsored by the International Bank for Reconstruction and Development in collaboration with the Government of Guatemala. (Washington: International Bank for Reconstruction and Development. 1951. Pp. xviii, 305. $5.00.)

Public Finance and Economic Development in Guatemala. By JOHN H. ADLER, EUGENE R. SCHLESINGER AND ERNEST C. OLSON, in collaboration with the Research Department of the Banco de Guatemala. (Stanford: Stanford University Press. 1952. Pp. xix, 282. $5.00.)

An International Bank Mission, headed by Dr. George E. Britnell, has surveyed Guatemala's potentialities for development "in order to enable the Bank to make recommendations with respect to the general directions in which such development could be most fruitfully undertaken and the conditions required for its success." In the report, published by the Bank, the Mission states that its development program has been influenced by three criteria. It has endeavored to allocate resources, first, "into fields which promise early . . . improvements in income and the standard of living"; second, into fields which promise cumulative improvements in income and the standard of living; third, to accomplish these two "without imposing an excessive strain on the country's ability to maintain a sound balance of payments position."

Accordingly, top priority is given to the promotion of coffee, the main export crop, and to the mechanized development of the richest but underutilized food-producing area. Coffee production offers the greatest possibilities for early returns and is also the "outstanding potential source of the increased revenue and foreign exchange needed to carry out a national development program." At the end of the tenth year of the proposed plan, the Mission expects coffee exports to be fifty per cent greater than the present level. The highway development plan, which accounts for a large percentage of total development expenditure, is also designed to facilitate the rapid expansion of valuable output which will produce foreign exchange quickly. The mechanized food pro-

duction program is expected to provide "a prompt and substantial increase in foodstuffs at reduced prices . . . [and] a better supply of raw materials for industry."

The first criterion which influenced the Mission's recommendations is an application of the marginal analysis and, by definition, will produce the greatest addition to real national income that could be obtained from given resources at any one time. The third criterion is used more as a note of caution limiting the scope of the development program than as a guiding principle for determining the desirable contents of that program. However, the marginal principle (first criterion) is not necessarily compatible with the growth (second) criterion. For example, if instead of being invested in conformity with the principle of short-run marginalism, more capital were invested in developing an economic structure which would yield a higher rate of growth than existed formerly, although the level of real national income would be lower in the short run, it would be higher in the long run.

As indicated, criteria one and three, based upon marginalism and prudence, are quite adequately satisfied in the plan; but how much emphasis has the Mission placed upon its second criterion? The growth criterion may best be satisfied if a "concatenation of industries' is developed. Such a "concatenated" structure has these attributes: first, an increase in the output of any one consumers' good or export, x, may increase the demand for and the output of other domestically produced goods which, in turn, react back and stimulate the demand for and the supply of x. The process then repeats itself. If the supplies of the various consumers' goods act as incentive goods to the other producers, or if the demand for the consumers' goods is complementary, such a concatenation may easily occur. Moreover, it should be possible for any major industry to serve as the initial stimulus for the expansion of the rest, in contrast with an export economy where the fates of the other forms of economic activity are completely dependent upon the vagaries of the export crops.

Secondly, the "concatenated" industries utilize a large volume of inputs which can be produced, or are available, at home. Whenever the output of consumers' goods is stimulated, in the manner just described, further production or fuller utilization of inputs is induced. Additional incomes are thereby generated and the relatively unskilled and underutilized labor force may obtain further training. This, in turn, enables real incomes to grow further since increased output of goods and exports may be stimulated either by higher incomes or by greater productivity of the inputs. Thus, the growth process is started over again. Such an economic structure does not necessarily involve any contempt for the principles underlying the gains from trade. Needless to say, this is not a short-run process, especially in backward areas; but is the process of growth ever a short-run affair?

Given this analysis, how far has the Britnell Mission's plan been influenced by its growth criterion? The Mission gives top priority to the development of coffee, corn and cotton production, but is noncommittal concerning the priorities of industrial growth. Thereby, the plan's ability to satisfy the

Mission's growth criterion is somewhat lessened. Food, exports, cotton and textiles are mildly "concatenated" to provide the foundations for economic growth in the sense discussed above. However, the Mission does not specify that the development of the textile, shoe and leather industries should receive priority over the development of the beverages industry. The choice as to which industrial products are to be developed is an important one. An economic structure based upon the coffee, food, cotton, textiles, shoe and leather and livestock industries may very well satisfy the growth criterion. On the other hand, an economic structure based on coffee, food and beverages may be unable to satisfy this criterion. The fortunes of coffee will affect those of the latter two; but it is difficult to see either how an increased demand for food or beverages might be induced any other way, or how an increased demand for one of the latter two could stimulate substantial growth in the others. What domestic inputs would be stimulated, and would such a structure provide training for labor?

The heavy orientation of this medium-run program towards criteria one and three may not be unjustified since it may be necessary to increase the relative emphasis upon projects which mainly satisfy these criteria, if the most desirable projects according to the growth criterion are unable to cope adequately with the foreign exchange and inflationary dangers. A long-range development program, however, should definitely place major emphasis upon the growth criterion, since the main value of a development program is its ability to create an economic structure which will generate its own rate of growth at a higher level than existed formerly.

This interesting report will probably be read by many people who will be called upon to implement development programs in Guatemala and in other countries. Such people, particularly, would profit more from the Mission's report if it had developed more fully the factors which influenced its decision to place major emphasis upon criteria one and three instead of upon the growth criterion.

The authors of the second volume under review have undertaken a type of study which is essential to a rational formulation of any program for economic development. Their study examines the impact of the Guatemalan fiscal operations upon the economy, the effect of these operations on the rate of economic development, and the extent to which the fiscal system can contribute to economic development. Since an important way in which fiscal policy may influence the rate of economic growth is through its effects upon the profitability—both before and after taxes—of different industries, the authors devote some attention to the impact of the fiscal system on business. Here, they analyze the effects of taxes upon resource allocation by determining the different tax burdens borne by various industries and the effect of the tax structure upon the form of business organization, the size of business firms and the structure of production.

An extremely suggestive and interesting observation is made concerning an indirect relation between the tax system and the structure of production. Since the market structure is very conducive to tax shifting—about eighty per cent

of the total business taxes are shifted to consumers—it is concluded that taxes weigh most heavily upon products having high income elasticities of demand. From this, one may infer that inferior goods consumed by the nonbusiness sector, which bears the incidence of these taxes, and luxury goods, consumed by businessmen (in the broad sense of the term) who shift these taxes, would gain from taxes which could be shifted, while taxed products which have very low price elasticities of demand would not suffer very much. Unfortunately, the available information precludes any more definite statement as to which products would be affected by these indirect effects However, if the products which are hurt by these taxes are those whose development the government is trying to stimulate, then the use of such taxes may be inimical to the government's economic development program. On the other hand, in Guatemala taxes which can be easily shifted curtail consumption and thus may be effective anti-inflationary devices. Therefore, it is to be hoped that the authors may in a future study evaluate the desirability for economic development of a tax structure which is based heavily upon taxes which can be easily shifted.

Fiscal policy can also influence the rate of economic growth by combating inflation, which often is induced by a development program, and by mitigating the impact of cyclical fluctuations. The authors, therefore, raise three basic questions to be answered in the latter part of the book which is mainly concerned with aggregates. First, is the revenue system "adequately flexible for a process of gradual expansion of general economic activity *without* inflationary price increases?" Second, is the present fiscal system capable of stemming "an inflationary tide" which may result from development? Third, what is the "proper degree of revenue flexibility" if the impact of cyclical fluctuations is to be mitigated?

Since a large part of the revenue depends upon the volume of imports which, the authors believe, increases more than proportionately with real income, it is stated that the fiscal system is sufficiently flexible to finance the gradual growth of output, if inflation is avoided. It is, therefore, maintained that a strong case can be made for continuing to rely heavily upon the yield from import taxes as a major source of government revenue. It is to be feared, however, that this policy recommendation may be misunderstood by the fiscal authorities. The case for a continued heavy reliance upon import taxes must presuppose that exports will grow proportionately with imports. Such a presupposition is not without justification because a large growth of exports is planned by the Britnell Mission in the near future. But, how long is this growth of exports likely to continue? If imports tend to rise more than proportionately with real income and if exports do not, will not the resulting balance of payments difficulties force the volume of imports to conform to the available foreign exchange reserves? Import tax revenues will not be able to continue to grow at the present rate since the growth of imports will be restrained by government decree. Furthermore, it is probable that a long-range development program will reduce the relative growth of exports to real income.

Therefore, since the long-run growth of exports cannot be assumed to equal the growth of imports—before government intervention—the fiscal authorities should be cautioned that they may be forced to modify the tax structure,

gradually, to rely less heavily upon import duties for a major part of government revenues.

The authors' analysis of the "proper degree of revenue flexibility" to mitigate the impact of cyclical fluctuations, and of the revisions in the tax structure which are designed to correct an inflationary problem, are further examples of how their policy recommendations and analyses give thoughtful consideration to the unique structure of underdeveloped countries and avoid the facile application of the usual economic rules of thumb which have emerged from the experiences of industrial countries.

JEROME L. STEIN

Wesleyan University

Evolución Histórica de la Industria Siderurgica Chilena e Ibero-Americana. By CARLOS SANCHEZ HURTADO. (Santiago, Chile: Editorial Nascimento. 1952. Pp. 398.)

There are few Latin Americans today who do not want to industrialize their countries. Those who oppose the establishment of heavy industry—specifically an iron and steel industry—are almost as uncommon. There are now iron and steel industries, or more or less well-advanced plans for bringing them into existence, in Brazil, Chile, Mexico, Argentina, Colombia, Peru, and Venezuela. Even the smaller nations are thinking in terms of establishing metal fabricating industries. The iron and steel industry has come to represent economic maturity in the southern republics of the hemisphere.

The present volume deals with this problem in two parts. The first is a study of the development of the iron and steel industry in eight countries in South and Middle America other than Chile; the second and larger half concerns the development of that industry in the shoestring republic. The author, a Chilean, is particularly interested in the development in his own nation, and is concerned with the industry in the other countries principally in so far as it throws light on the situation in his own.

Sanchez Hurtado is an enthusiastic supporter of the new Huachipato steel plant which first entered into production in Chile in 1950. He examines with considerable care the problems which have faced this enterprise, and how they are being overcome. For instance, he looks at the prospective markets for the plant's products, concluding that a large enough market is likely to exist in Chile for a plant of the present capacity of Huachipato, and hints that in time there may even be sufficient markets in Chile and the neighboring countries for a plant capable of producing at the most efficient capacity, according to United States standards, which would mean a plant about three times the present size of Huachipato. His analysis of this possible expansion of plant rests fairly heavily on the likelihood of an export market for a considerable amount of output in Argentina, which will probably never have an iron and steel industry capable of meeting its own needs. It rests less heavily on the possibilities of exporting to the neighboring countries of the Pacific coast of South America.

The author examines the raw material situation of the industry, analyzing

Chile's resources of iron, coal, electricity and other required products. Although there is plenty of iron, and of most of the others, the possible Achilles heel is coal.

Problems of location, and difficulties in obtaining a labor force and technical skill, are also discussed. Finally, Sanchez Hurtado describes in some detail the financial arrangements which were made with the Export-Import Bank. He stoutly defends the terms of the agreement with the Eximbank, terms which because of their requirement that American engineers and technicians administer the plant in its five years, have come in for a great deal of attack in Chile.

This study is a product of the Seminar in Economics of the University of Chile. This seminar, directed by some of the country's leading economists, has been responsible for some of the best studies of Latin American economic life which have been made. The present work takes its place as one of the most distinguished of these research projects. It is scholarly in its research and scope. It has an exceedingly useful bibliography appended.

ROBERT J. ALEXANDER

Rutgers University

The Economic Development of Iraq. Report of a Mission organized by the International Bank for Reconstruction and Development at the request of the Government of Iraq. (Baltimore: Johns Hopkins Press. 1952. Pp. xi, 463. $5.00.)

This report might have been sub-titled: The Art of Spending Large Funds Wisely, or, Inflation in Moderation. The International Bank's mission to Iraq, headed by Ivar Rooth, with John C. de Wilde as chief economist, had the unique and enviable task of making recommendations for an economic development program in a situation in which the problem is not a cramping shortage of funds but, rather, the effective use of a virtual flood of revenues for development.

In accordance with an agreement reached in 1951, the three internationally owned oil companies operating in Iraq have undertaken to raise oil output, which amounted to 6 million tons in 1950, to some 30 million tons per year by the end of 1955 and to turn over to the Iraqi government half of the profits before the deduction of taxes. On this basis it is anticipated that over a five-year period the government may receive net revenues amounting to as much as 214 million dinars from oil alone. (One Iraqi dinar equals £ 1 or $2.80.) Under the terms of a law passed in 1950 all such oil revenues are to be used for developmental purposes.

To carry out the proposed five-year program, the government will have "to gear itself" to an annual rate of development expenditures which at the end of the period will need to be about ten times the total public capital outlays (ID 5,200,000) in 1950-51. The mission's report stresses the dangers involved and certain of the basic requirements. "The experience of other countries in process of development illustrates that it is not easy to spend money rapidly

and efficiently on well-conceived projects. . . . Such a rate of expenditure will be achieved only with great effort and by careful planning."

The mission's major prescription for preventing a severe and disruptive wage and price inflation is for the government to allow liberal use of its sterling income from oil to pay for imports. Measures to curb credit expansion are also proposed. Lacking reliable information at almost every point, the mission must skirt many of the critical issues: Granted the wasteful use of manpower on the land, can a sufficient labor force be recruited rapidly, and can it be done without a serious drop in agricultural production? Certain types of skilled labor are already in short supply; will the development projects tend to siphon off this supply and disrupt the existing industries and services? In the face of the obvious difficulties posed by the unprecedented situation and the lack of information, the mission provides a thoughtfully conceived set of general guide-lines, including a recommendation that a committee of economic experts be formed to keep watch on the nature of the changes that the economy is undergoing to provide a basis for more detailed planning.

The report provides a brief, but careful, analysis of the underlying economic problems of the country and a detailed description of the major problems and potentialities within the agricultural and industrial sectors. Iraq has a relatively rich natural resource base. In addition to its fabulous oil resources, it has a vast land frontier. Official estimates suggest that the amount of "cultivable" land is almost three times that under cultivation. Projects for the storage of the flood waters of the Tigris and the Euphrates can open up large new areas for settlement, while the drainage of lands which have deteriorated owing to salting could do much to raise the present low productivity of agriculture.

Industry is as yet little developed, but here too the mission finds conditions favorable to fairly rapid expansion. In oil and natural gas the country possesses a cheap source of power and fuel as well as an important source of raw materials. An expanding agriculture will provide a variety of materials for processing. The mission makes specific suggestions as to what industries might be expanded and what new industries might be established, based on an analysis of the prospect for efficient production on a competitive basis.

The existing transport system is found to serve the present needs of the country adequately and, with the implementation of programs for improvement of the road network and the railway system, transport capacity should have no difficulty in meeting the growing requirements of agriculture and industry.

The great hurdles to rapid economic progress are seen to be not in the realm of natural resources and financing, but in the "underdeveloped" state of the human resources and in the generally backward-looking and often exploitive institutional arrangements which dominate the Iraqi scene. The Iraqi *fellah* lives in the direst poverty and suffers from debilitating diseases; he is illiterate, ignorant and tradition-bound. Also, he is exploited (he sometimes has to turn over as much as six-sevenths of his crop to the landlord) and he is overtaxed.

Throughout the report, the mission stresses the importance of improvements in the quality of the human resource. Several chapters are devoted to measures for raising the levels of health and education and expanding the basic community services. The most advanced thinking in these fields is drawn upon and the whole subject is treated with thoroughness and insight. An unusual feature of the report is a section on community planning and the rôle it can play in improving the living conditions of the population and the efficiency of the public services.

Far less satisfactory is the treatment afforded the hurdle to progress posed by existing institutions. The report refers to a few of the difficulties—for example, the tendency for new and improved land to fall almost entirely into the hands of the big landowners, and the excessive, monopoly-creating protection of existing industries—but the few minor changes proposed would seem to fall far short of providing for a "climate" in which the ambitious targets set could possibly be achieved. Here, of course, is involved the difficult question of how far a "foreign" mission can and should go in discussing underlying social, political and economic institutions. Under any circumstances, one might question the advisability of setting targets and proposing programs involving unprecedented rates of progress, especially for a country which for many centuries has remained virtually static, without at the same time specifying fully the conditions for such progress. Expert missions have the opportunity—and, it may be argued, the responsibility—of treating problems within their usually narrow terms of reference in a context which relates economic development to broad social issues and provides a challenge to aim at progress on a truly broad front. Within its own terms of reference, the mission to Iraq has provided a competent and valuable report.

HARVEY S. PERLOFF

University of Chicago

Challenge and Response in the Middle East. By HEDLEY V. COOKE. (New York: Harper & Brothers. 1952. Pp. xiii, 366. $4.00.)

Recent events in the strategic Middle East should not baffle those who have read Hedley V. Cooke's basic and timely study. The book explains in some detail the circumstances which underlie the unrest and revolution in Egypt, the thorny problems which stand in the way of a rational settlement of the Iranian oil question, the rapid strides which Israel and Turkey have made since the end of World War II.

Challenge and Response in the Middle East is an account of the economic, political, and social conditions of the area, showing how these conditions arose, are perpetuated, and what can be done to improve them. The book opens with an introduction and follows with chapters on each country of the region—Iran, Iraq, Syria, Jordan, Israel, Egypt, Turkey, Lebanon, Saudi Arabia, and Yemen. A chapter on regional planning and one on the future conclude the study. The country chapters provide, for each political entity of the area, factual and analytical material on the general background; the nature,

application, and the results of the various plans which have been made for economic and social improvement; and recommendations for future action.

This study should appeal to a wide audience, and find a place on the reserve reading shelves of college courses in economics and geography. Both well-written and scholarly, it could be read with profit by those interested in this strategic region and America's rôle in international economic development. In particular, economic planners, the institutionalists, regional and agricultural economists, geographers, as well as development engineers, will be amply rewarded by a study of this document.

In part, this work is the story of what exaggerated emphasis upon nationalism, xenophobia, tradition, together with unenlightened class interest, can mean in terms of physical impoverishment. It is easy to see how the Middle East pattern of income distribution has retarded the rate of economic development, with its great inequality between very narrow upper and very wide lower limits, and with its heavy emphasis upon incomes from property as against those from personal effort.

Hedley Cooke offers no pat solution for the problems of the area. Although he apparently favors the regional approach, he is cognizant of its pitfalls. He seems to have considerable confidence in the capacity of Point IV to aid in the development of the area—but one wonders, in view of the magnitude of the task, if sufficient funds are available to do more than scratch the surface of the problem.

Two possible avenues to the development of the area—private investment and trade promotion techniques—are not explored in any detail, although the investment experience of the oil companies in the Middle East and the results achieved by the American and European trade promotion programs afford good case material on both methods.

The study sketches, somewhat too briefly perhaps, the work done by the Middle East Supply Center, an Anglo-American organization created during World War II to assure a minimum flow of essential goods to the region and to maintain its political stability. This organization, which had the confidence of virtually all groups of the area, was liquidated at the end of hostilities together with Lend-Lease. In view of the substantial achievements of the Middle East Supply Center during World War II, its continuation, together with Lend-Lease, into the post-war period might have proved of considerable aid in the development of the Middle East.

Economic planners will find little solace, but much food for thought, in the author's analysis. The Middle East has not suffered from any dearth of planning. The plans, by and large, have not been carried out and this work spells out in some detail, the reasons for these failures. Institutionalists, on the other hand, will find much evidence in the pages of this book, of the power of the institutions—especially those of land tenure—to influence the level and the pattern of economic life.

Hedley Cooke assembles and analyzes the results of recent scholarly investigations and adds material and insight gleaned from several years residence in the region as a Foreign Service officer. The result is a top-notch contri-

bution to our understanding of the problems of the Middle East, readably presented with objectivity and competence.

MAX J. WASSERMAN

Howard University

The Soviet Financial System: Its Development and Relations with the Western World. By MIKHAIL V. CONDOIDE. (Columbus: Bureau of Business Research, College of Commerce and Administration, The Ohio State University. 1951. Pp. xiii, 230. $4.00.)

This book is notable for the fact that it represents the first attempt by a Western student in almost fifteen years to undertake anything like a systematic survey of the Soviet financial system. It seems curious that this aspect of Soviet economic activity should have received so little attention in the West, particularly since this is one field in which the Soviet government's restrictive information policy has been applied with relative leniency. A considerable volume of descriptive as well as statistical material on Soviet finance continues to appear from Moscow. While this material is notoriously fragmentary and often difficult to interpret, it does present the meticulous student with a promising opportunity to examine and appraise the functions of Soviet finance and its rôle in Soviet economic development.

Professor Condoide's study, unfortunately, does not take full advantage of this opportunity. Its positive contribution is a description of the legal-institutional framework of Soviet finance. On this level, it examines the organizational structure and operational details of the banking and credit system, defines the legal status of money and gold, describes the revenue and expenditure composition of the government budget and outlines the methods of financing foreign trade. The material is illustrated with a fair collection of summary statistics and supplemented by a detailed bibliography and some interesting documentary appendix material. However, the usefulness of this descriptive material is impaired by some notable omissions (*e.g.*, no mention of the State Insurance System, no data showing outlays on "internal security"), by factual inaccuracies (*e.g.*, faulty statements on savings bank interest rates and services, p. 45; wartime changes in tax rates, p. 96), by errors of interpretation (*e.g.*, confusion between national budget and financial plan, pp. 77 and 160), and by some irrelevancies (*e.g.*, 40 pages of text and appendix devoted to Soviet foreign policies and violations of treaty obligations).

In its analytic aspects the study is disappointing. In his attempts to analyze the functional aspects of Soviet finance and to assign finance its proper rôle in Soviet economic organization, Condoide is hampered by a superficial understanding of Soviet economic processes. His statements that "the allocation of labor is authoritative" (p. 13), that "all economic activity is financed by the state" (p. 20) and that "the state is the sole producer and distributor of commodities" (p. 20) depict the central authority as a ubiquitous and omnipotent decision-making entity and completely ignore the important rôle that decentralized decisions and nongovernmental organizations play in Soviet

economic activity. His comments on the functions of money, credit and prices are often vague and sometimes contradictory. Thus he claims, on the one hand, that "the government's investment plan is carried out automatically, as a result of the allocation of physical resources, no matter how it is financed" (p. 14), and concludes, on the other hand, that "Soviet banking, credit and monetary policies provided practically unlimited funds to promote industrialization; hence what provided employment was this spending and not planning as sometimes assumed" (p. 47).

In his analysis of financial policy the author shows a tendency simply to reproduce, without further comment, the ambiguous and cryptic official Soviet stereotypes which purport to explain the objectives and rationale of their financial operations. His efforts to probe behind these stereotypes show little insight. Thus, while he takes issue with the Soviet claim that gold reserves are related to the tempo of socialist development, he assumes that the pegging of the ruble to gold will make gold reserves "to a much greater extent than heretofore, the foundation and security of the Soviet currency system" (p. 58). Condoide dwells at length on past Soviet failure to hold in check the inflationary forces generated by Soviet industrialization, but neglects to point out that, at least since 1948, the hard lessons of monetary instability seem to have been learned. In this connection, a discussion of the use of the budget surplus as a fiscal counterpart to bank credit creation, and other deflationary techniques applied by the Russians with conspicuous success in recent years, would have been welcomed.

To the general reader, this book may prove helpful as an introduction to the financial institutions of the USSR; because of its analytic deficiencies, however, it cannot be recommended to the specialist.

HANS HEYMANN, JR.

The RAND Corporation
Santa Monica, California

Labor in the Soviet Union. By SOLOMON M. SCHWARZ. (New York: Frederick A. Praeger. 1952. Pp. xviii, 364. $6.00.)

Dr. Schwarz notes at the outset of his book that he is considering only certain topics within the larger field of subject matter which the title connotes. His concern is with the theory and practice of Soviet labor policy in four areas: the labor market, wages and the standard of living, hours and conditions of work, and social insurance. Furthermore, he deals only with that portion of the total labor force which works for hire, the "workers and employees." They comprise the overwhelming bulk of the industrial (and urban) labor force, but they are less than half of the total.

If there is a theme in his book, it is that Soviet labor in the four areas is far from as well off as it could be were official policy otherwise and as the Soviet press would have the people at home and abroad believe it is. This means something different in each of the areas, and the book can therefore best be reviewed one area at a time.

Compulsory control is the aspect of Soviet policy in the labor market which receives most of the author's attention. The discussion centers on the labor laws of 1938 and 1940. In certain of their provisions, designed to strengthen plant discipline and curb labor turnover through "moderate" compulsion involving pressures and penalties, these laws are an extension of past laws. Schwarz describes the development of this type of legislation in great detail, giving special attention to its origin in the transition from the New Economic Policy to the First Five-Year Plan. In their more drastic provisions, however, the laws of 1938-40 represent "a fundamental change in the labor relationship" (p. 100): the introduction of workbooks, the establishment of a labor draft, provision for the compulsory transfer of certain skilled personnel, and the ordering of criminal punishment for quitting a job without permission of the employer. Even here, the author finds some precedence in earlier legislation.

These laws gave to individual ministries and enterprises compulsory control over the labor in their jurisdiction. Whether the absence of a central administration of labor control (except for the training program) made this compulsion any the less pervasive from the standpoint of the worker, the author does not clarify: ". . . practically all elements of . . . compulsory labor were at hand . . . lacking [only] an administrative setup to make it operate as a coordinated compulsory organization of work processes" (p. 119).

On the question of postwar developments in the labor market, Schwarz is very brief. After noting that extraordinary measures adopted during the war were apparently dropped after 1947, he says only this: "The enforcement of the decree of . . . 1940 seemed . . . uncertain in 1945 and 1946. This . . . was . . . a passing phase. The government . . . strove . . . to overcome the weakening of their rigid system . . . [and] in the field of labor policy . . . seemed ready for a consistent pursuit of the course . . . strikingly expressed in the 'reform' of June, 1940" (pp. 128-29).

The chapters on wages and the standard of living cover the movement of money wages and consumer goods prices, in order to show what has happened to real wages since 1928. The presentation is detailed, but the author does not attempt, as others have, to construct an index from the incomplete price data. Consequently, his conclusions on the movement of real wages are in general terms: Real wages dropped about 50 per cent from 1928 to 1932, rose about 20 per cent from 1935 to mid-1938, and then fell continuously until 1946. A rise after 1946 is still going on; but he is sure that real wages in 1928, 1938 and probably even 1940 are "far from attained" at present. He summarizes the views of other analysts on this question and takes issue on certain points. Within an area of general agreement on developments since 1928, his is the relatively pessimistic view of recent wage trends.

The author estimates that "socialized wages" (*e.g.*, public health) show a trend which more or less parallels the movement of real wages; therefore, "it can hardly be concluded that they . . . make up for the latter's decline" (p. 249).

Three-quarters of the book is devoted to the sections above on the labor market and wages and living standards. The treatment of the third subject,

hours and working conditions, includes the time-organization of production, from the seven-hour three-shift day with continuous work week used early in the plans to the present eight-hour day and 48-hour week; the practice of "socialist competition" (up to 1937); the widespread use of overtime and the violation of restrictions on the use of female labor (called a "decline in labor protection"); and the deterioration in work safety. On postwar developments the author gives only a summary impression, namely, that hours and the work-day are the same as in 1940, although overtime is probably not as prevalent, and that with respect to the decline in labor protection and safety, "a certain leveling off . . . seems to be in the making" (p. 303).

The final section of the book, on social insurance, is a short but comprehensive survey of legislation in the field. The theme is that social insurance, more than providing security for the worker, is a weapon in the drive to raise productivity and strengthen labor discipline.

This book evaluates Soviet labor policy in terms of its effect on the Soviet worker, and it finds that the cost of the policy in freedom and material well-being has been very high. As a result, many of the goals of the revolution and the five-year plans are seen betrayed. Other books on Soviet labor have reached the same conclusions,[1] but Schwarzs' treatment of the theme is noteworthy because he develops it more systematically, in greater detail, and with more documentation—and because he is able to include wartime developments. (His treatment of the postwar period is a limited one, as noted.) Furthermore, the book has unique value in the person of the author, a lifetime student of Russian and Soviet labor, whose commentary on specific points and issues will be of lasting benefit to specialist and nonspecialist alike.

In the end, on the grounds of both universal ethics and the lofty aims of the Bolshevik revolution, Soviet labor policy must be judged as Schwarz has judged it, in terms of "its impact on the every-day lives of workers and employees" (p. vi), all other conditions aside. In the meantime, however, it must also be evaluated (if not judged) in terms of the chiefly impersonal ends which it was designed (also) to achieve—the increase of production and labor productivity, the lowering of costs of production, the effective distribution of the labor force, etc., in other words, the solution of the basic economic problems.

Schwarz does not address himself to answering these questions, but he does touch on them frequently, a fact which may lead the casual reader to associate his secondary observations with the extensive foundation built to support his main theme. This may not always be justified. For example, while examining the beginnings of compulsory control, he makes this observation concerning the labor market of the 'thirties, following the abolition of unemployment insurance (1930): "the market automatism of labor supply and demand vanished" (p. 51). To accept such an unqualified statement, the reader

[1] The two most recent are M. Gordon, *Workers Before and After Lenin* (New York: Dutton, 1941) and L. E. Hubbard, *Soviet Labour and Industry* (London: Macmillan, 1942). The first puts the conclusions in even stronger terms than Schwarz does. The second, while reaching essentially the same conclusions, places them in perspective alongside other aspects of the total picture.

must be given as thorough a presentation of all the aspects of the labor market as he is of only one of them. Compulsory control over labor distribution and discipline may have been the dominant (if not exclusive) factor in the "market" after 1940, but it does not seem to have been such in the middle 'thirties (according even to evidence elsewhere in this book). On the contrary, enough of the characteristics of "demand and supply," as economists understand the term, were still evident prior to 1938-40, that the term may be used as an apt generalization of much of the market's activity.

WARREN W. EASON

The Johns Hopkins University

Economic Systems; Planning and Reform; Cooperation

The Cost of Industrial Movement By W. F. LUTTRELL, assisted D. A. COCHLIN, F. G. DAVIDSON, and J. F. THOMPSON. Occasional paper No. XIV of the National Institute of Economic and Social Research. (New York: Cambridge University Press. 1952. Pp. ix, 104. $3.75.)

In the British Coalition Government's famous White Paper on Employment Policy for a "High and Stable" Employment, and in the policy of all subsequent governments, regardless of party, the problem of industrial location has loomed large. This was natural since in certain "depressed" areas, of which the biggest were South Wales and the North East Coast, unemployment in 1933-37 was at least double the average for the whole country, and there was, besides, a large reserve of unoccupied women of working age. In the Distribution of Industry Act, 1945, also fathered by the Coalition Government, development areas were formed out of these depressed areas and manufacturers virtually forced to build any new factories there, if anywhere. This is perhaps the nearest approach Britain has made to positive planning, and it was rendered possible by the postwar shortage of building materials. If manufacturers in "congested" areas proposed to build extensions to their main factory rather than branches in the development areas, they might not get the necessary allocation of timber and steel.

Free-enterprise enthusiasts will naturally want to know the extent of the resulting damage to the economy; and in a most laudable attempt to assess the economic costs, if any, of their own policy of insisting on branch factories rather than extensions, the Board of Trade, the responsible government department, financed Birmingham University, University College, London, and the National Institute of Economic and Social Research, to enquire into the relative costs of the different locations. This volume is a preliminary "interim" contribution, but the general plan of enquiry is explained in Sir Henry Clay's preface.

Mr. Luttrell has devoted himself to comparing new branch factories, mainly in the shoe industry, started in places unused to the industry, though not

necessarily in a development area. He finds that in the first years of their establishment new branch factories have, on average, much higher total costs, but that they gradually manage to reduce costs so that by the third year the four branches studied that long had 30%, 19%, 13% and 4% higher total costs than their main factory. These different percentages were associated with differences in the training of new workers and in the provision of a nucleus of skilled workers. Distance of branches from main factories was also important because of accessibility to skilled workers in the old district and to management services of the main factory.

An unexpected discovery of these studies is the lack of knowledge of firms about the precise burden of their costs. Once the goodwill of firms had been obtained, with full access to their accounts, definite and fairly exact conclusions might have been thought possible. In fact, firms themselves seem in the dark or, if they appear to themselves in the light, it is often a false light. Mr. Luttrell comments, for instance, on the undue disregard of overhead in comparison to direct labour cost, though overhead costs may be two or three times as great. Whether firms know their own costs or not, however, is in the present British situation not so important as might be supposed. With full employment, unfilled vacancies and lag in filling housing needs it is often not a matter of getting labour cheaper or operating cheaper generally in one place than another, but of getting labour at all. Many a Birmingham firm that cursed the government for insisting that it build a branch in a development area rather than extending its main factory must now be thanking its stars (but not of course the government) for this bit of State planning. For with the present prosperity and over-employment in Birmingham, labour is not to be had, though still available in areas some distance away.

Mr. Luttrell is to be congratulated on presenting his case studies clearly and yet in detail. After a brief introduction (Chap. 1), he is careful to explain the scope and methods of his enquiry (Chap. 2 and 3) before describing (Chap. 4-5) his four detailed cases, three in the shoe and one in the engineering industry. But he is not just descriptive. In his final chapter he puts forward some tentative conclusions as to the importance of training labour and the difference between a branch thirty miles and a branch sixty miles from the main works—conclusions which cannot be said to be novel or to arise very clearly from the cost comparisons. But in this pilot enquiry it is good that the author is careful to contrast the straight comparison between branch and main works with the more relevant comparison between branch and an equivalent *extension* of operations at the main works. If main works is not fully utilized, extension is, by spreading overheads, likely to be cheaper. But this assumes that labour can be secured at the main works location. Under present British conditions of full employment this assumption is not realistic and Mr. Luttrell is right in soft-pedalling the comparison of branch with extensions to main plant, though it is the more logical comparison. We look forward eagerly to further publications of this government-sponsored research.

Marx Against the Peasant: A Study in Social Dogmatism. By DAVID MITRANY. (Chapel Hill: University of North Carolina Press. 1951. Pp. xiii, 301. $4.50.)

Populism in Eastern Europe has its roots in the deep discontent of the peasant class. The land hungry (often landless) subsistence farmer was primarily interested in the redistribution of land. Populist writers borrowed from the physiocrats all the arguments in favor of an "independent" peasantry, protected by a benevolent government against feudal and urban exploitation. Mitrany's book is a good example of Populist writing. As a disciple of Proudhon, he felt impelled to attack what he thinks are twin enemies of the independent peasant: the liberal and the Marxist economist. Both "regarded the agrarian problem from the angle of production rather than from that of social organization," both looked upon "large-scale production . . . as the first condition for general well-being." Capitalist farming and collectivization lead to the same end—the destruction of the small family holding, which, after all, should not be looked upon "merely as a means of living but as a way of life."

Large-scale farming (according to Mitrany), as exemplified by the English inclosures and the latifundia in Italy and Eastern Europe, did not raise the productivity of the soil nor emerge as "a better system through free competition" (p. 11). This is true, of course, of latifundia, a feudal anarchronism, which kept the peasants in bondage (hence overcrowding, malnutrition, and low productivity). The inclosure movement, on the other hand, complemented the industrialization of England by providing a surplus of agricultural produce to feed rapidly expanding towns, which at the same time provided new avenues of employment for those not wanted on the land. If, however, the surplus farmer had been permitted to stay on the land, the result would have been as disastrous as in prewar Poland, for example, where minute subdivision of the land reduced peasant holdings to agricultural slums.

There is a lot of nonsense in Mitrany's book about "peasant mystique," about "the pernicious effects which followed from superimposing Western capitalism upon a simple peasant society," and about rural overpopulation—the worst type of concealed unemployment—which, perverting the concept of full employment, he assumes to be a contributory factor to full employment! "A country eminently agricultural . . . is a country eminently poor and socially and economically backward." This basic fact, expressed by a Populist writer whom he quotes (p. 28), leaves Mitrany unconvinced. But farming in industrialized Western Europe—depending, of course, upon availability of arable land—succeeded in balancing cash crop and diversified production, which neither the latifundia type of large-scale farming nor the small subsistence farmer in Eastern Europe was able to achieve. Still more important is the fact, that the peasant class in Western Europe retained its social organization, and became solidified as the core of a traditionally conservative society which, unlike the semifeudal East, was not averse to rapid industrialization and absorption of the landless in urban centers. This is what Stolypin (Russian Prime Minister, 1906-1911) proposed to do in his great land reform in Russia. He had in mind the creation of a loyal well-to-do peasantry as a

balance against the city proletariat, an ill-fated attempt to stave off revolution!

Peasant-dominated governments inspired by Populist ideals had their chance in power after the First World War, and muffed it. Hasty land reforms gave "millions of poor sharecroppers and landless laborers . . . a new status as formally [!] independent peasants even if economically many were not better off than dwarf owners" (p. 94). The division of land resulted in a "reduced supply of food to towns" (p. 95). Mitrany chides Western economists who "simply looked upon the fall in the production and export of cereals as proof of a decline in productivity" (p. 100). Why, farming had changed now from farming for the market to farming for subsistence! The peasants, "in an economically stronger position, satisfied first their own needs before they started producing for the market" (p. 101). In fact, a change from backward latifundia into backward small holdings brought about a deterioration in the balance of payment position and a further decline in the standard of living in these countries.

Thus redistribution of land—creating innumerable dwarf holdings—actually retarded the economic development of these countries. Poverty and unrest, as before the war, became a permanent feature, especially after the disastrous price drop of farm products in the early 1930's. Military *coups d'état* and court intrigues finally succeeded in eliminating reform governments under peasant leadership. Yet Mitrany leaves the impression that a "victorious" Populism had emerged as a sort of peasant Third Force (see Ch. 10, "Not Capitalism, Not Socialism"). On the contrary, its ideology has now been discarded as no longer useful. Peasant leaders, now in exile, have accepted the Western type of agricultural organization (*i.e.*, capitalist production with its legal guarantees of property holding, profit making, noninterference, etc.) as their ultimate goal. This they pledged in the so-called "Williamsburgh Declaration of 1952," a platform for restoration of Western-oriented regimes. On the other hand, former Populists who remained and joined the various front governments seem to have consented (or been forced to consent) to the destruction of small-scale farming and to rapid collectivization on a Russian model as a *fait accompli.*

FREDERICK SETHUR

The City College of New York

Money and Banking; Short-Term Credit; Consumer Finance

The Growth of a Central Bank. By L. F. GIBLIN. (Melbourne: The Melbourne University Press. 1951. New York: Cambridge University Press. 1952. Pp. xi, 363. $5.00.)

Soon after extensive Australian financial legislation was passed in 1945, the Commonwealth Bank of Australia commissioned Professor Giblin to write a history of that bank covering a period as far back as the previous major

financial legislation, the Commonwealth Bank Act of 1924. The Bank could not have chosen an author with more intimate knowledge of the subject: Giblin was one of the first professional economists to have been employed by the Commonwealth government; from 1935 to 1942, he was a member of the Commonwealth Bank Board, and from 1938 to 1946, he was chairman of the Conmmonwealth Advisory Committee on Financial and Economic Policy. The resulting volume can be considered a kind of personal memorial to Professor Giblin; he died as it was in press.

This history, even though "official" and commissioned does not suffer from an excess of reticence. Giblin makes wholly clear the shortcomings of both men and laws in the struggles of the Commonwealth Bank to achieve central banking stature. He reveals the limited vision of the Bank's founders, the inadequacies of the laws under which it operated, and finally the limited objectives of those who managed the Bank during its early years.

One of the greatest mistakes was the effort to use the English model without sufficient adaption to local problems. The Commonwealth government patterned the Commonwealth Bank after the Bank of England. It tried to endow the Bank with similar powers and similar responsibilities. But the Commonwealth Bank could not discharge these responsibilities with these powers primarily because the pervasive influence of banking tradition did not operate as it did in the City of London. The Australian banks were able to challenge the financial influence of the Commonwealth Bank with impunity. Only the financial necessities of war finally forced the government to give the Bank real central banking powers. Perhaps the chief of these new powers was an enforced rule concerning the character and amount of commerical banking reserves.

Professor Giblin explains at length two banking developments not adequately reported elsewhere. During the war, Australian banks were not subject to excess profits taxation; as a result, one of the war duties of the Commonwealth Bank was to control the profits of banks. This was done by adjustment of the special accounts which will be mentioned in the next few sentences. The second feature of general interest was the introduction of secondary reserve requirements, somewhat similar to those the Federal Reserve sponsored in the early postwar years. This plan was the outgrowth of a system of war finance by which bank participation was managed by direct allocation to special accounts and not by voluntary subscription as in the United States. The obligations were similar to the treasury deposit receipts (TDR's) used by Great Britain except that the accounts were of indefinite maturity. The system worked well; as a result it was carried over into the permanent financial structure by legislation in 1945.

The reader of this book is forced to reflect ruefully that one of its major forecasts has already been proven wrong. Giblin concluded that high interest rates would never again be used as a device for restraint of credit. He adhered to this view, not for the reasons that are sometimes associated with the name of Keynes, but because he expected all central banks to be dominated by their respective treasuries and treasuries would universally want low rates.

This book is unfortunately marred by the lack of a subject index. The

chronological organization of the book requires a constant shift in attention among several subjects, such as the general economic scene, fiscal policy, monetary policy, and the state of external and internal banking reserves. This results in a choppy narrative style; a reader becomes easily confused with dates and events for which there is no ready remedy except a search of preceding sections. Nevertheless, the results are worth the work.

ROLAND I. ROBINSON

Northwestern University

Inflation. By PAUL EINZIG. (London: Chatto and Windus. 1952. Pp. 223. $2.50.)

Dr. Einzig has provided a stimulating contribution to the current literature on inflation. What he has to say is not as novel as he implies; nor is the rigor of the analysis likely to appear adequate at all times to the academic economist. Nevertheless, he is on the right track, in the opinion of this reviewer, and his argument is at least provocative when not compelling.

The author rejects what he calls the usual "static" definition of inflation as an excess of purchasing power over what is required by the attainable level of output at the current price level. In its stead he offers a more "dynamic" concept of inflation as "a state of disequilibrium in which an expansion of purchasing power tends to cause, or is the effect of, an increase of the price level" (p. 22); and which "is sufficiently pronounced and persistent to set into motion a spiral of rising cost-of-living, wages, cost of production, and monetary requirements and volume of money" (p. 23). What he considers to be novel in his definition of inflation is, I believe, the emphasis on price changes as the causal factor, with monetary expansion the result ("price inflation"), and on the dynamic interaction of monetary inflation and price inflation. Any upward movement in prices is likely to set off a continuous spiraling movement which the monetary authority is either unable or unwilling to check. Armed with this definition Einzig examines the relation to inflation of a wide range of circumstances and measures of policy. There is space here to mention only a few of these.

When the "undertone" (state of expectations?) is inflationary, increased taxation will not have a disinflationary effect, according to Einzig. Direct as well as indirect taxes will result in higher prices and income demands. These, in turn, will necessitate monetary expansion to sustain the higher price level. This is true even when the tax revenues are utilized to provide social services. For social service benefits tend to be considered as cost-free additions to income which are received as a matter of right. Consequently, income claims will rise in order to offset the income-reducing effect of the taxes levied. For this reason and because of a tendency toward over-full employment, the welfare state is inherently inflationary in Einzig's opinion.

The author effectively puts to rest certain naive notions about the disinflationary character of price increases. Surprisingly often in the recent debates over inflation one has come upon the argument that open inflation was preferable to suppressed, that the removal of subsidies on food prices would be

disinflationary or that the rise in the prices of imported goods was disinflationary because it mopped up purchasing power. These arguments, Einzig points out, ignore the dynamic nature of inflation wherein price rises lead to monetary expansion, to further price rises, etc.

His emphasis on price inflation leads him to reject the arguments of the "mild inflation forever" school. First, he doubts whether inflation with its dynamic character could remain mild. But, further, he suggests that price inflation may combine the disadvantages of both inflation and deflation. Price inflation is not employment-stimulating; rather, monetary expansion is required to follow it merely to keep employment from falling. Conceivably, continuous price inflation could accompany both underemployment and monetary stringency.

This no more than begins to touch upon the wide range of issues to which Einzig addresses himself with equally provocative results. There are comments on the post-Korean experience of the United Kingdom and a discussion of alternative policies for that country which, unfortunately, have been rendered less timely by the events of the more than one year which elapsed between the completion of the manuscript (as indicated by the date of the preface) and the publication date.

One shortcoming, in the opinion of this reviewer, is the failure to make explicit the assumptions which underlie the analysis. Whereas the traditional concept of inflation was adequate for a highly competitive economy where no problem of unemployment is recognized, Einzig's definition is tailored to a modern economy wherein competition is limited and the government is committed to the maintenance of full (or high-level) employment. It is only when "price makers" (to use Scitovsky's term) dominate markets that prices can be raised in advance of an expansion of purchasing power. And it is the full-employment commitment which is crucial in compelling the monetary authority to permit monetary expansion following on price rises; for the failure to do so would mean reduced output and employment, not reduced prices. This is implicit, I think, throughout the book, but its explicit statement early in the volume would have been helpful.

JOHN POWER

Williams College

La Monnaie. By ROBERT MOSSÉ. Bilans de la Connaissance Economique. (Paris: Lib. Marcel Rivière et Cie. 1950. Pp. 205.)

This book is the first of a series of "surveys of economic knowledge." The author undertakes to present a sketch of our knowledge of monetary affairs and ideas as they have developed in the last fifty years; "it is certainly not 'a digest', for it is directed towards a synthesis rather than towards an analysis . . ." Obviously to attain this goal in 130 pages (the rest of the book is taken up by Howard Ellis' Introduction, by the "Observations" of two other authors, and a bibliography) a careful selection was necessary; rather than to charge the author with omissions we should try to understand the viewpoint which guided him.

We notice first that the monetary theorist's dislike for problems of credit

institutions is not fully overcome; in discussing, *e.g.*, the controversies concerning the issue of banknotes, which filled the 19th century (p. 63), the author does not even mention the rôle of bills of exchange (or, more generally, of eligible paper) as collateral for banknotes.

Secondly, as far as monetary doctrine is concerned, the book virtually stops with 1932: theoretical problems arising in connection with Keynes' *General Theory* are not discussed at all, except for a few paragraphs about the multiplier in Chapter 3. This omission is the more serious, since this chapter, after briefly stating the quantity theory in Fisher's version, presents Aftalion's theory of monetary revenue (R) determining the price level (R = PQ). Mossé does not seem to realize that Aftalion's formula is not an explanation but an identity (p. 79: "attention is concentrated on the equilibrium between the monetary revenue designed for purchases and the total values of sales of goods and services"); nor that money does not even appear in the equation. Otherwise, he would have realized that it was precisely the achievement of the *General Theory*, by introducing functional relations, to relate income to the quantity of money, and to convert a mere identity into a set of determining equations.

Thirdly, even where the theoretical thinking of the past is summarized, brevity rather than clarity seems to have been sought. In discussing the quantity theory, Fisher's distinction between normal relations and transitional period is at least implicitly presented (p. 74), but no definition and analysis of the concept of the velocity of circulation of money can be found, except the statement that, according to the quantity theory, it is either "constant" or "always neutralized by the 'velocity' of commodities (see Marget)." (How shall the reader understand this?) In discussing the quantity theory in the Cambridge version (Chap. 3), the author overlooks the difference between the *ex ante* nature of the *k*-coefficient and the *ex post* character of the transactions velocity. In expounding the multiplier, Mossé asserts that "it is necessarily associated with period analysis," though the Keynesian multiplier is static, and Haberler's article of 1936, to which Mossé refers, deals with the Keynesian, not with the serial multiplier. In a footnote Mossé raises the question: "Is not the multiplier simply another name for income velocity?" though the former is a pure number and the latter has the dimension of time.

For these defects in the theoretical "synthesis," the reader is, to some extent, compensated by the vivid sketch of the state of monetary thinking before 1914, and, in particular, of monetary history after 1914. The American reader will be somewhat surprised by the stress laid repeatedly on the dispute between "metalism" and "nominalism," which fortunately did not infect Anglo-Saxon and Scandinavian economists. Mossé greatly overrates the influence of Knapp's *"étatistique"* theory of money; it was almost unanimously rejected by both German economists and German bankers; the paper-money inflation of 1914-23 was, as in other countries, the result of muddled thinking and indecision in an emergency, not of "nominalism." How, by the way, is the claim that metalism was generally accepted around 1900, compatible with the prevalence of a "nominalistic" quantity theory of some sort among Anglo-Saxon economists?

There are added to the main text of the book two sets of "Observations."

Those by Professor Triffin, of Yale, are mainly concerned with exchange-rate problems, which were excluded from Mossé's discussion. The Observations furnished by Professor Federici of Milan undertake to justify Mossé's neglect of Keynesian thinking, which "does not contribute anything basically new to the knowledge of the monetary process as it can be gained from a modern interpretation of Fisher's theory" (p. 133). Federici, however, read Keynes in his own peculiar way. Keynes is supposed to treat "as secondary and subordinate the function performed by money precisely if it is not spent" (p. 123); most of Keynes' readers had been under the impression that he assigns a rather exaggerated rôle to liquidity préference. "In the modern theory the monetary quantity is reduced to a secondary role if compared with the role played by the volume and proportion of expenditure" (p. 129). This is true for certain post-Keynesian applications of his theory and easily explainable from the high supply elasticity of credit money since 1933. In the *General Theory,* however, the quantity of money is treated as the only strategic parameter, whose changes govern those of the interest rate, of investment, income and employment.

Space forbids the further enumeration and discussion of details. Points mentioned must suffice to justify the reviewer's feeling that, despite some undeniable merits, this *bilan* has not attained its aim of being a synthesis of monetary theory.

HANS NEISSER

New School for Social Research,
New York City

Geld und Gesellschaft. By WILHELM GERLOFF. (Frankfurt am Main: Vittorio Klostermann. 1952. Pp. 288. DM 25.00.)

This is a valiant and interesting, but only partially successful attempt to develop a social theory of money. The author has covered much of the ground previously in other books, particularly in his *Die Entstehung des Geldes und die Anfaenge des Geldwesens.*

The major part of the book consists of a sociological and anthropological analysis of the origins of money. Its economic significance is discussed only marginally, and relatively superficially since the author's conclusion is that the origins of money are to be found in the social sphere. They have little, if any, relationship to economic necessity or even convenience. Money entered the economic area only late in its development; when it did, however, its importance grew immensely.

It is the author's thesis that the three major stages of the development of money are closely related to three human sources of cultural development: instinct (*Trieb*), habit (*Gewohnheit*) and reason (*Verstand*). The basic instinct, we are told, is the desire for recognition of one's achievements, and resultant social distinctions. This instinct causes the hoarding of valuables. The origin of money lies in its function as a hoarding device. From the habit of using money for this purpose developed the practice of using it as a means of payment for noneconomic functions, such as the purchase of wives,

expiation of sin, or the settlement of reparations. Reason finally turns it int barter-money and somewhat later into a tool for more general economic ex change. "Der Weg vom ritualen Geldgebrauch zum rationalen ist der We des Funktionswandel des Geldes."

Money thus had its origin in tribal customs, frequently of a magic o mystical nature. At first they involved the making of gifts and at a late stage the exchanging of gifts. The objects that were repeatedly used for thi purpose because of their general desirability—usually luxuries, such as ring —slowly developed into money. They were desired, however, not because the gave the holder economic advantage, but personal recognition and soci distinction. Economic man is a fiction; *homo ambitiosus* is vivid reality, an primarily explains the origins of money. This part of the thesis is develope at great length.

Barter is the crucial step which gave money economic significance. Wit the expansion of economic institutions, the use of money grew from a to for barter to a general means of payment and pricing. This was not a simpl causal relationship, for money in turn assisted enormously in economic e pansion. Money finally reached its greatest height in the liberal capitalisti economies of the nineteenth century. As various forms of governmental co trols are imposed upon these economies, money loses some of its functions, an declines in importance.

The author's attempt at a detached, anthropological approach does n always succeed. For example, from the proposition that "correct" money "just" money he concludes that such money requires a monetary unit whic maintains its value. Money which declines in value leads to spendthrift co sumption, paralyzes the will to save, and thus endangers social welfare. Th conclusion—mistakenly generalized—has considerable, but not absolut validity. In America, for instance, it is quite possible future economic we fare requires a measure of such "paralysis," *i.e.*, an increased consumptio function.

A great deal of the analysis is truly fascinating, but it is buried in an ocea of verbiage. This will trouble Americans considerably more than German for the latter have been confronted with such writing in their social and ec nomic literature for many years. It is repetitious, badly organized, and e ceedingly verbose; much that is obvious is not only stated, but frequentl repeated. Many a straw man is set up only to be knocked down successfull The book deserves to be carefully edited and, together with some of t author's other writings in this field, should be made available to the Englis speaking world.

HANS A. ADLER

Washington, D.C.

Money and Economic Activity—A Selection of Readings in the Field Money and Banking. Edited by LAWRENCE S. RITTER. (Boston a New York: Houghton Mifflin Company. 1952. Pp. viii, 404. $2.95.)

An up-to-date book of readings in the field of money and banking has be

lacking in the United States since the late 1920's. In the decade of the First World War this need was met by Phillips[1] and in the following decade by Ivan Wright.[2] But during the 1930's and 1940's a hiatus existed. Thus, it remained for Professor Ritter to provide the first book of general readings as a supplement to single-text material for the 1950's.[3] This he has done in creditable fashion.

The book is divided into five parts, the first of which deals with "Money and Commercial Banking." It contains eighteen selections on the nature of money, banking, and a money economy; asset management of commercial banks; adequacy of bank capital; and the supervision of banking, including proposals for reform.

Part II, containing thirty selections, is concerned with "Central Banking." The topics covered are methods of credit regulation, factors related to member bank reserves, interest rates, war finance, and proposals for reform in monetary policy.

The next Part deals with "The Treasury and Monetary Policy," and includes twenty-two selections. The main headings are gold and the monetary system, monetary aspects of treasury operations, and central bank-treasury relations.

Part IV, "The International Economy," presents five selections on international finance, the balance of payments, gold movements, and the dollar shortage.

The final Part concludes with four selections on monetary policy and economic stability.

The book is on the whole well organized, with a thread of continuity from beginning to end, in so far as is possible in a collection from many sources. A few exceptions, however, detract from the organizational pattern. Selection 5 introduces multiple expansion of bank credit and the methods of credit control prematurely, and is repetitive with Part II, Chapter 6 on "Central Banking." Selection 6 on the par collection system would fit more logically in Part II on "Central Banking." Also, this reviewer feels the inadequacy of the space given to "Money and Commercial Banking" (Part I)—98 pages, compared with 165 pages on "Central Banking" (Part II), and 70 pages on "The Treasury and Monetary Policy" (Part III). The central problem of determination of the value of money receives no attention, and inadequate space is accorded bank loans and investments.

The individual selections are well chosen from a variety of authoritative sources and with an eye for different points of view. Large use is made of the wealth of material growing out of the Douglas Committee investigation and of publications of the Board of Governors and the Federal Reserve Banks. The editor introduces each selection with a helpful summary of the leading ideas.

[1] Chester A. Phillips, *Readings in Money and Banking* (New York, 1916) 845 pages.

[2] Ivan Wright, *Readings in Money, Credit and Banking Principles* (New York, 1926) 1,081 pages.

[3] This statement does not overlook *Readings in Monetary Theory* by a Committee of the American Economic Association (Philadelphia, 1951), 514 pages. By design this excellent collection of the best articles was directed to one segment of the field.

Teachers of money and banking should find Ritter's volume a welcome contribution to available teaching materials—especially in two-semester courses that devote considerable time to problems of central banking and monetary management.

G. W. WOODWORTH

University of Michigan

Business Finance; Investments and Security Markets; Insurance

Share Ownership in the United States. By LEWIS H. KIMMEL. (Washington: Brookings Institution. 1952. Pp. xi, 140.)

Share Ownership in the United States was prepared by the Brookings Institution at the invitation of the New York Stock Exchange. Lewis H. Kimmel directed the project. Its successful completion, however, was the result of the cooperative effort of thousands of individuals, business concerns, and financial groups. The study concerns the ownership of publicly owned corporations. Proprietorships and partnerships were excluded, as was ownership in family and closely held corporations. The sole test for the inclusion of a stock issue was whether there was sufficient public interest in such issue. It should be noted that publicly owned corporations are considered to be those which are owned by individuals in their own right, in contrast to government ownership.

The study is divided into two parts. In Part I the objective is to determine the nature and characteristics of *shareholdings*. Each listing in the stock transfer book is counted as one shareholding. If a person owned stock in ten different corporations, this was counted as ten shareholdings. The analysis of shareholdings is based upon usable data furnished by 2,991 corporations covering 3,954 stock issues. Of this number 1,022 were preferred stocks; 1,436 of the issues were unlisted. It is estimated that the present study covers about 25 per cent of all publicly owned stock issues.

Apparently this is the first time any study has included a classification of shareholdings by type of holder. Reference will be made, however, to only a few of them. The shareholdings of record, when classified by type of owner, refutes the popular notion that women own most of the nation's securities. The figures indicate that, while more women than men are holders of common and preferred stocks combined, men not only own a greater number of shares but the total market value of their holdings is greater than that for women.

Part I presents, apparently for the first time also, an analysis of shareholdings by states and geographic divisions. The heaviest concentration of shareholdings, both for common and preferred stocks, is in the state of New York, a fact attributable in part to the numerous holdings registered in the names of nominees, brokers, insurance companies and other types of financial institutions. Shareholdings of record are also classified according to size of business and type of business.

Considerable attention is devoted to an analysis of shareholdings registered in the names of nominees of banks and trust companies, as well as in the

names of brokers and dealers. The purpose is to show how such shareholdings are distributed among the several classes of beneficial owners. This is probably the first attempt to analyze these aspects of share ownership. The shareholdings of record for the reporting corporations are adjusted to show how they would appear if there were no shares registered in the names of nominees and brokers and dealers.

Part II analyzes the number and characteristics of share owners. It is estimated that 6,490,000 individuals in the United States are share owners in publicly owned corporations. The study reveals that owners are relatively more frequent among people 50 to 59 years of age than in any other age group; also that there is a direct relationship between share ownership and education. Also affecting share ownership, as might be anticipated, is the level of income.

With respect to occupation, share ownership is shown to be highest for administrative executives, about 45 per cent of these being share owners. Professional workers rendering personal services—doctors, lawyers, and others—rank fourth with 12 per cent. Share ownership is found to be relatively more frequent in families of one or two members, and the proportions of families and individuals owning shares is highest in the far western states—about 12 per cent for families and 6 per cent for individuals. Share ownership per family is found to be relatively highest in cities with a population of 25,000 to 100,000. It is estimated that the average number of different issues per individual share owner is 4.1. Also, more individuals own shares in manufacturing companies than in any other type of industry.

Life insurance, savings accounts, United States Series E Bonds, annuities and pensions, outrank publicly owned stocks as a form of investment. Following stock ownership as a form of investment is ownership in other government bonds, privately held stock, real estate mortgages and bonds, and corporate bonds.

The major reasons prompting individuals to acquire stocks are given as the desire for profit value appreciation (28 per cent), and a desire for income from dividends (22 per cent). Only 1 per cent of those questioned indicated they were motivated by a desire to hedge against inflation.

The study indicates that many people have a direct stake in American industry and business enterprise. Not only are there some 6,490,000 individuals who own stock in publicly owned corporations, but millions more have an interest through their ownership of bonds and other credit instruments, as well as indirectly through ownership of life insurance and savings accounts.

The book is brief (140 pages), and yet it covers the subject in a satisfactory manner. Each tabular presentation, and there are many, is well explained.

The inferences to be drawn from this study, however, will have to be those of the reader. The author sets forth the various estimates and the analysis of the data in a dispassionate manner. No moral is drawn as to whether or not a particular state of facts is "desirable" for our economy.

This study is probably the most comprehensive that has yet been made of stock ownership, either as to shareholdings or as to share owners. It provides a wealth of information as to the ownership of the corporate sector of our

economy and, while the book will be particularly valuable to those intimately concerned with this subject, it should be required reading for all who have an interest in the welfare of our economy.

International Economics

The Economics of the International Patent System. By EDITH TILTON PENROSE. (Baltimore: The Johns Hopkins Press. 1951. Pp. xv, 233. $4.00.)

The central purposes of this book are to examine the economic significance of the right of an inventor to obtain patent protection not merely in one country but throughout most of the world and to evaluate the precautions most frequently taken by governments against abuse of this right. Though Mrs. Penrose regards the economic arguments usually used in support of the patent system as open to serious question and qualification, she provisionally accepts them in order to focus attention upon the significance of the type of patent grant that covers inventions already patented and worked in foreign countries. The principle of such grants has been generally adopted, she finds, because of pressures from large industrial countries, exporting firms, patent lawyers, and spokesmen for so-called internationalism, in spite of persistent and often well-founded doubts on the part of various small and underdeveloped countries that their interests are served thereby.

Mrs. Penrose concludes that when the geographical scope of patents is expanded by licensing foreign inventions, there is little reason to expect a significant increase in the rate of invention or industrial development and that, for the world as a whole, any such social gains as may appear are likely to be outweighed by heavy social costs taking the form of higher prices and less efficient use of resources. Nevertheless, she thinks that an international extension of patent protection is necessary to cope with problems as to the location of industry that would otherwise be created by national patent systems. If an invention could be patented in only one jurisdiction, patents would tend to concentrate in the larger industrial countries, and, in so far as there were requirements that the patents be worked, plants would be constructed, not in the best locations, but in the patent-granting jurisdictions covering the largest markets and thus offering the largest potential profits from patent monopoly. Moreover, concerns not possessing the patent would erect plants in other countries in order to escape control by the patentee. Thus tactics related to patents might overcome economic considerations bearing upon industrial location, and the export trade of patent-granting countries might be reduced by the frequency of the incentives to produce abroad rather than deal with the patent-holders.

Two ways of reducing the social costs of the international extension of patent rights are analyzed by Mrs. Penrose. The first, compulsory working of the patent within the patent-granting country, she finds to be not only in-

effective but also conducive to an uneconomic multiplication of plants, some in undesirable locations. The second method, compulsory licensing, she considers an effective and flexible way of preventing most of the more serious restrictions upon industry, especially the monopolistic activity of certain international cartels and the withholding of new techniques developed abroad that are needed by domestic industry.

In developing her central argument, Mrs. Penrose relates it to the more important provisions of the International Convention for the Protection of Industrial Property. She concludes that although the convention is one-sided it cannot be blamed for the defects of the international patent system and that the effort to use it to eliminate working requirements has been sound. However, she recommends that its restrictions upon compulsory licensing be eliminated, that use of this device be encouraged, that nonindustrial countries be exempted from the obligation to grant patents upon foreign inventions, and that the possibility be explored of using the Convention to alleviate restrictions on trade and industrial activity incident to unregulated patenting.

This reviewer finds nothing to criticize in the execution of this book, except possibly that the argument is presented too compactly. Important questions are put, and clear and persuasive answers are given. However, the general plan of the book has certain defects. The chapter on the history of patent laws is only tangentially related to the central theme, and, though well done, is too brief to be useful to the audience to which the rest of the book is addressed. The chapter on the rationale of national patent systems summarizes and criticizes arguments on behalf of patent laws, but, having been conceived as introductory and therefore brief, it does not reach conclusions as to the effect of the patent system upon industrial development within a single country. For lack of these conclusions, the discussion of the effects of an international extension of patent rights has a provisional flavor. Its logical place is in the second volume of a two-volume work, but volume one is missing. It is to be hoped that Mrs. Penrose will supply it later. But in spite of this gap in the exposition, the present volume is one of the best among the few works concerned with economic aspects of the patent system.

CORWIN D. EDWARDS

Washington, D.C.

Survey of United States International Finance, 1951. By GARDNER PATTERSON and JACK N. BEHRMAN. (Princeton: Princeton University Press. 1952. Pp. xi, 325. $2.25.)

With the appearance of its third report, it is hoped that the International Finance Section of Princeton University will no longer regard the publication of an annual summary on international economic issues of the United States as experimental, but will conclude that the survey has established itself along with the annual reports of the Economic Commission for Europe, Organization for European Economic Cooperation, Bank for International Settlements and governmental institutions. Unlike the ECE and BIS reports in that it eschews opinion, and differing from the OEEC and governmental writing which must

ignore the existence of differences of opinion even when taking a side of an issue, the *Survey* has won its place as one of the indispensable annual additions to the library of economists concerned with international economic matters.

The *Survey's* purpose is to record facts and issues. Unlike the ECE it is not interested in the imaginative use of statistics to make a point. Its statistical contribution is limited to the presentation of balance of payments data for the United States, slightly reworked to eliminate inconsistencies and for clarity.

Its discussion of issues, moreover, is not confined to "international finance" but ranges over a wider field into commercial policy, European integration, and Point Four. Finance in the narrow sense, in fact, is not a concern of the authors, for the chapter headings include nothing on the foreign exchange value of the dollar, nor do they discuss international capital movements in detail with the use of the weekly data. Entirely properly, the *Survey* is directed to finance in the broader sense.

Within this area, it is possible to take exception to the emphasis given by the authors to the events of 1951. The nationalization of the Abadan refinery in Iran and the collapse of commodity prices from the giddy heights reached in March of that year are both discussed only tangentially, though they cast their shadow far into the future in the United States' financial relations with the rest of the world. No mention is made of the United Nations' experts' report, *Measures for International Economic Stability,* although the other two UN reports by experts are referred to.

The usefulness of the *Survey,* already high, might be enhanced by the inclusion of an annotated bibliography of documents and articles bearing on issues. Much of this is already made available, but strewn through the footnotes, from which it must be exhumed via the index.

What must be admired is the authors' capacity to remain above the battle and to describe issues and even to characterize reactions but not to take sides. Most of the adjectives used are descriptive but involve no subjective evaluation. The nearest thing to a slip in this regard is the reference to an article by John Foster Dulles as "lucid." This departure from the high standard of aloofness otherwise maintained may perhaps be forgiven on Freudian grounds in a Republican year.

Massachusetts Institute of Technology

The Pattern of United States Import Trade Since 1923. By JOHN H. ADLER, EUGENE R. SCHLESINGER and EVELYN VAN WESTERBORG. (New York: Federal Reserve Bank of New York. 1952. Pp. 136.)

In this study, covering the period 1923-1950, the authors have investigated the U.S. demand for imports, compiling separate series for the main geographic areas of origin. For each area—with a few unimportant exceptions—there are value, price and quantity series for crude foodstuffs, manufactured foodstuffs, crude and semi-manufactured materials, and finished manufactures, as well as

for total imports. This detailed treatment is of particular help in studying problems that have a varying geographical impact, such as the effect of our business cycle on imports from the Sterling Area, and thus on the British balance of payments.

Two conclusions stand out. Confirming earlier findings, the authors agree that the level of economic activity and real income in this country were the primary determinants of our imports from each area.

The second, more surprising, conclusion is the estimate of price elasticity for finished manufactures, particularly those from Western Europe (the European Recovery Program countries). The authors believe that a change of 1 per cent in the relative[1] price of this category would change our imports (in the opposite direction) 2 to 3 per cent in volume terms. For many commodities, the price elasticity tends to be greater the larger the proportionate change in price; and it also becomes greater the longer the time period considered. This is contrary to the belief of many students, some of whom have felt that the elasticity for this group may even be less than 1.

Some of the other findings regarding price are similar to those for the domestic economy that F. C. Mills' work[2] has shown. Over the cycle, the greater the variation in price, the less the variation in quantity, and *vice versa.* Prices of primary imports fluctuate more than those of finished manufactures. Geographically, this means that the ERP export price structure is more stable than that of Latin America or the outer Sterling Area, but the ERP volume of sales, and thus employment, faces greater fluctuations.

The possibility of the price mechanism serving to facilitate the substitution of foreign for U.S. goods in the U.S. market is greatest for finished manufactures. Not only would the total volume of our imports of this group rise if their prices fell, relative to competing U.S. goods, but their relative share of our market would also increase.

As compared with the prewar period, our gross national product in real terms has risen more than the volume of imports. For raw materials and semimanufactures this may indicate a change in the fundamental relationship to domestic activity, although the authors believe that for small year-to-year changes the prewar relationship still holds. For finished manufactures, however, it is thought that the relatively greater rise in foreign export prices compared with competing U.S. goods is a principal cause of the downward shift since prewar in the proportion of these imports to domestic output, and that a reversal of this price shift would restore the prewar ratio.

The postwar decline in the proportion of our imports coming from the ERP countries was noticeable also in the interwar period, and reflected the downward trend for finished manufactures imports in general. Part of the recent relative loss may have been caused by the fact that World War II stopped almost all imports from continental Europe, thus transferring U.S. demand to other sources (including domestic suppliers). But part of the shift can be

[1] Relative to the price of finished manufactures from other areas including those produced in the United States.

[2] *Cf., e.g., Prices in Recession and Recovery* (New York, 1936), Ch. III.

attributed to the great increase in our demand for durables, items which have always been negligible among our imports.

Within the ERP group the relative decline has been greatest for those countries whose export prices have risen the most, proportionately. The average price level for the group as a whole has also risen relatively to our prices; this, the authors believe, led to a shift away from ERP goods. Their conclusion, however, may not be the only important explanation; it is possible that the dislocations caused by the recent war curtailed supplies so much—particularly in the export trades, whose connections with this country had been disrupted for almost six years—that the mechanism worked from a shortage of goods to a price rise. In other words, the greater the shortage of a particular product, the greater the relative price rise, and the greater the relative fall in its share of our imports.

One assumption which may be questioned is with respect to the elasticity of supply of finished manufactures to the U.S. market. The authors assume almost perfect elasticity over the relevant range. It is true that goods can be shifted from the ERP home market if the suppliers so desire. But this may not be as simple as the authors imply. Even if prices are more attractive in this country, it may be difficult to establish sales outlets—in fact, in view of the vagaries of our market and tariff policies, it may not be worth the risk. For example, let us assume a strong demand for automobiles in this country. On a purely comparative price calculation it might pay to ship autos here rather than sell them at home or in other markets. However, there may not be the necessary repair and service stations to maintain the cars; there may not be the dealers' outlets willing to stock new—and, to the American consumer—strange products. Moreover, if the sales effort is successful, a tariff may be placed on this item, ending the imports and making the previous sales efforts worthless. Hence, the supply inelasticity may be quite high, particularly when the normal inertia supplements the other obstacles. So long as other profitable markets exist into which entry is less difficult, the greater profitability of the American market may not offset these other fears.

It is in the price policy implications that we find another possible weakness in the study, although one that is probably inevitable. Based on historical data, the study shows that a decline in the relative price of finished manufactures imports would increase the volume of sales so much that total receipts would rise. The obvious policy inference is for foreign manufacturers to reduce costs and prices. But what cannot be certain is the reaction of U.S. competitors. If the per unit margin is sufficiently large, our prices can be reduced to meet this outside threat; in other words, although a relative fall in foreign sales prices would boost imports, any serious inroad into domestic markets might result in sharp reactions by our own producers, even ignoring the further complication of pressure to increase the tariff. The only two widespread decreases in foreign finished manufactures' prices relative to U.S. competitors were those associated with the devaluations in 1931 and 1949. In both cases the income effects on sales were so strong that producers may not have been aware of the influences of the accompanying price changes. It will be recalled that 1931 was a year of almost steadily declining incomes and output in this country, while in mid-

1949 the recovery from the preceding recession began. If, in a future situation, foreigners reduce their prices relatively, and if it is clear that a successful penetration of our markets results from this policy, U.S. producers may react pricewise more vigorously. Hence, although a relative price reduction might aid foreign sales, in fact, it might also call forth corresponding cuts by U.S. firms, so that the gain to the foreign seller would thus be much less than is implied by the calculated elasticity.[3]

Another weakness of the study is the assumption regarding the constancy (over the relevant ranges) of the price and income relationships. In the study both arithmetic and logarithmic equations were employed. The former implies that the marginal propensity to import was assumed constant; the latter implied "that the income and price elasticities are constant throughout the entire range of observations and independent of the size of absolute changes" (p. 49). Yet, it may well be true that at different levels of national income, a given change in incomes will produce different changes in imports. In a depression, with much unemployment of domestic resources, increases in income may go mainly into the purchase of domestic supplies, while at near-full employment a greater impact will be felt on foreign supplies because of the tighter domestic supply situation.[4] Again, the impact on specific commodities, and thus on different areas, may also change with changing income levels. The 1950 upswing in U.S. economic activity after the Korean outbreak boosted certain imports much more than a similar upturn from a lower level would have done. Steel and chemical imports from Western Europe rose much more than would have been the result had the economy been at, say, only 75 per cent of capacity.

Implicit in the preceding criticism is the observation that a given change in national income (or GNP), even from the same absolute level, may not always have the same impact on imports. An upturn resulting from rearmament may so concentrate demand on, say, the domestic steel industry, as to result in capacity operations—and thus the need for more imports—at a national income level lower than an upturn resulting from government expenditures on public works. In the former, steel imports (and thus total imports) would rise more, proportionately, than in the latter case, even though the proportionate change in national income were the same in both possibilities.

It is exceedingly difficult—if not impossible—to allow for these various possibilities. Indeed, even if the functional relationships suggested could be deduced, the extra work required for the refinements and the more complicated mathematical equations resulting, would probably not be justified. Hence, these observations are to be interpreted as qualifications, rather than rejections, of the findings.

Business Administration

Economics of Business Enterprise. By LEONARD A. DOYLE. (New York: McGraw-Hill. 1952. Pp. xiii, 343. $5.00.)

Professor Doyle has written a text whose aim is to make marginal analysis the central theme and integrating principle of an upper division and graduate training in business. In particular he puts forward techniques that he believes would enable practicing businessmen to apply economic analysis directly to managerial decisions. In addition, Doyle tries to give the student the equivalent of a rigorous course in intermediate economic theory. His book is an unusual combination of topics, some of which are treated in an unusual manner.

The first two chapters are introductory, setting the discussion of the business enterprise system in a broad frame. Doyle describes the structure of the American economy through the device of an imaginary trial in which the private enterprise system is charged with suppressing competition and promoting monopoly. In the course of this trial, basic data describing the number, size, industrial composition of firms, profitability of corporate firms by size, national income variations, measurement, and sources are set forth. The use of the mock trial form helps to kindle interest in what might otherwise have been a dull presentation of data and statistical methodology.

The second chapter deals with two quite separate subjects. The first is the nature, problems, and structure of the firm. Combined with this discussion is a treatment of the rationale of a free enterprise economy, concluding with a crisp, penetrating discussion of the discrepancies between the rationale and the real economy. The contents of this chapter are excellent, though its organization leaves much to be desired.

There follow two chapters dealing with the nature of pure competition and demand, with emphasis upon the benefits to the individual businessman of escaping the rigors of competition, primarily by restricting entry. In explaining the operations of pure competition, Doyle works through an agricultural illustration, employing elaborate numerical computations as well as the routine geometric tools. The discussion of market demand is commonplace, but adequate.

In the second of these chapters entitled "The Behavior of Market Demand," Doyle discusses monopoly and imperfect competition, indicating briefly how they come to pass and their attractions to the businessman. The arrangement of topics is somewhat perplexing but the author's meaning is clear enough. Missing from this chapter is the basis for Doyle's conclusion (p. 330) that . . . ". . . the elasticity of demand *decreases* as the quantity is increased," which he says was explained in this chapter. The income pyramid described in detail by Doyle tempts one to infer, on the contrary, that the elasticity of demand frequently rises at lower prices and larger quantities.

As illustrative of imperfect competition, Doyle discusses the professions and retailing. His discussion of the professions is a cursory but interesting essay concerned as much with the socialization of medicine as with anything else. However, it contributes little to the author's fundamental objective and might have been omitted.

Doyle's discussion of imperfect competition among retailers is one of the more difficult parts of the book. It introduces some improvisations and variations on the break-even chart that this reviewer has not encountered before. In addition, it deals with various problems, among them "fair" trade laws, the mark-up method of pricing, and the reasons for diverse types of retail outlets. While this chapter covers important subjects and is anything but routine and unimaginative, it probably will prove troublesome to student and teacher alike because of the brevity with which major problems are touched upon. For the most part, the chapter sets up apparatus that will enable a retailer to decide how much it must sell at a given level of mark-up to break even and to cover its costs, including a target rate of profit. While retailers probably do think in terms of mark-ups rather than absolute price, the transformation of one into the other is hardly vital for basic understanding and might not justify the effort required to master it. Specialists in the subject of industrial pricing will, however, find it of interest.

In discussing the advantages of large-scale operation, Doyle covers more than is ordinarily treated under that head. He discusses at some length the determination of obsolescence costs and the suppression of new machines and methods. This chapter is careful and competent. The use of twelve involved diagrams, however, threatens real difficulty for even the best graduate students of business.

Like most other chapters, the one treating costs of distribution represents a collection of interesting and illuminating remarks combined under a framework of organization that is somewhat strained and novel. Much of this chapter is devoted to a discussion of vertical integration and the diverse movements of price and alleged differences in demand elasticity at various stages between raw material production and final purchase.

The most strategic chapter in the book is entitled "The Marginal Analysis and Practical Business Operation." It is here that Doyle elaborates the break-even chart, relating it closely to the marginal cost-marginal revenue equality of traditional price theory. In addition, reference is made to conventional business practice and the amount of information available to the average businessman. This section of almost thirty pages is tightly written. While no careful count has been made, the word "if" probably appears more frequently than any other, for supposition follows supposition and the reader is required to work through numerous successive examples. In effect, these examples require the reader to make some numerical calculation to determine whether revenue rises more than cost from a specific circumstance.

We learn in that chapter that the break-even and profit charts are the techniques that enable businessmen to apply economic analysis to managerial decisions. If I understand Doyle rightly, he concludes that economic analysis contributes to practical business operation by: (1) directing the decision-maker to ask whether a particular action contributes more to total revenue than it adds to total cost; (2) calling attention to the possible effect of output on unit cost; and (3) directing thought to the responsiveness of sales to price changes (p. 333).

The chapter which follows applies the break-even chart directly to decisions of multi-product firms, and completes the discussion of price and output decisions of the individual firm. Subsequent chapters are concerned primarily with general pricing practices and their social implications.

Chapters 11 through 13 deal with price leadership, uniform delivered price systems and price discrimination. These chapters depart little from the conventional treatment of these topics, though there are many statements that are not proved or shared by economists generally. They will not injure the advanced business student, however, for his prejudices are likely to run counter to Doyle's.

The last two substantive chapters attempt to explain the incomes of labor and management and discuss the interest cost and financial solvency problems of the individual firm. These chapters will do little more than afford an opportunity for teachers so inclined to introduce these topics. Apart from well-balanced statements about labor relations in general, the first of these simply makes difficult to comprehend the simple dictum that employers should not pay workers more than they contribute to total value of output. The final chapter, entitled "The Economics of Finance and Bankruptcy," touches on less familiar ground, but here again straightforward concepts are over-elaborated and probably obscured by the author's desire to say everything geometrically.

It is difficult to make general statements about a book that is so uneven in its separate parts. On the debit side, Doyle may have made a strategic error in making the book so short, or, equivalently, in deciding to do so much. Although his writing style is crisp and clear much of the time, the better-than-average student probably will find this book very difficult. Part of the student's difficulty will result from the book's organizational weaknesses. Especially in the arrangement of topics and sequence of ideas within individual chapters is improvement possible. The book also suffers from a shifting viewpoint. Business practices are discussed from the standpoint of owner profits and social benefit without clear indication of which viewpoint is being applied. Also, greater justification for the heavy reliance on the break-even chart than has been offered would be desirable. The reader waits in vain for discussion of the difficulties that are faced in applying it in concrete cases and for an examination of alternative methods that might be employed to obtain similar results. Finally, Doyle, as most other authors writing in this general field, makes numerous statements about business procedure or conditions that are unsupported. They are stated as if they were generally accepted conclusions, even when they are minority, though possibly correct, opinions.

On the credit side, Doyle undertook an eminently worthwhile task. The value of economic analysis for a practicing businessman has long been a major problem confronting college teachers and administrators. That this reviewer does not share Doyle's conclusion on this matter is irrelevant. Each reader can decide for himself whether or not Doyle has shown that refined economic analysis is an important aid to a practicing businessman. Doyle certainly has been intelligent, industrious and imaginative in trying to make economic

analysis relevant and useful to business operation. In addition, from my limited knowledge of the literature, Doyle has introduced refinements for break-even chart analysis that some will find useful.

The reader will almost certainly come away from this book with the feeling that it is intelligent, imaginative and sensible. Doyle clearly could write a lucid, original and illuminating book about business operation and decision-making. However, he did not quite reach the mark in this book.

A. R. OXENFELDT

The City College of New York

Marketing in the American Economy. By ROLAND S. VAILE, E. T. GRETHER, and REAVIS COX. (New York: Ronald Press. 1952. Pp. xviii, 737. $6.00.)

The appearance of this book was eagerly anticipated by many teachers in the field of marketing because of the recognized standing of its authors and because teachers were led to believe that a new approach to the subject would be taken. It does differ substantially from other widely used introductory texts in marketing.

The authors state at the outset that "We have a common meeting ground . . . in our conviction that students can best be introduced to marketing by a textbook whose primary point of view is the transcendent importance of this social institution as a vast and complex function of our free-enterprise economy." This statement together with all it implies to people trained in the social sciences serves well to characterize the book. Marketing teachers recognize that the subject can be approached in the manner suggested or primarily from institutional, functional, or managerial points of view. Inevitably there is something of each in any comprehensive treatment of the subject but primary emphases may differ and, in this instance, the emphasis is definitely upon the social and economic significance of those activities which have come to be included under the term "marketing."

The authors think of marketing as *the* directive force in a free-enterprise economy. Specifically, the two principal or basic tasks of marketing are stated as follows: (1) to direct the use of resources and allocate scarce supplies in conformity with existing demand, and (2) to aid in making consumption dynamic in conformity with changes in our ability to cater to human wants." Furthermore, the concept of "resources" is a broad one as it includes human as well as natural resources and "the political and economic institutional arrangements under which we live." It is likely that these broad concepts are foreign to the thinking of many teachers of marketing. Perhaps they will not find themselves in agreement with this conceptual pattern but at least their thinking will be stimulated by the ideas presented, particularly those in Part I under the title, "Marketing in Our Economy."

The book proceeds with Part II, Specialization and Integration in Marketing; Part III, Buying and Selling; Part IV, Pricing; Part V, Marketing within and between Regions; and Part VI, Marketing Efficiency and Control. Part II is particularly well organized. After an opening chapter on channels of distribution there are excellent chapters on collecting, sorting, and dispersing mer-

chandise and on organization of the flow of ownership. These are followed by a too short discussion of wholesalers and retailers. The authors then consider nonprofit agencies, nonowning agencies, and, finally, questions of stability and change in marketing agencies. In this latter chapter there is a short discussion of the historical development of marketing. While, to the reviewer, this is a most welcome addition to any introductory textbook on marketing, there is too little of it. Marketing students need more historical perspective. After reading many textbooks in marketing, students may well think that goods and services were first marketed about the time of World War I.

Part III on Buying and Selling comprises a number of very short chapters on buying, on selling of primary products, and on selling by manufacturers and distributors. They are too short to be reasonably comprehensive, particularly the one on selling of primary products. The marketing of farm products is given but scant attention anywhere in the book. The last chapter in this section, on nonprice competition, while good, again is too abbreviated, particularly in its treatment of aggressive selling as a nonprice weapon. A better balance of attention to subject matter according to its relative importance would have been gained if this part of the book had been expanded, with more attention to the activities of the manufacturer, the wholesaler, the retailer and, perhaps, other intermediaries as marketing institutions. This expansion would have overcome a possible criticism that the student may actually know little of such institutions after reading this text.

In Part IV the authors have compressed much on pricing and price policies into about one hundred pages. The topics and subtopics are well chosen and, while the discussion of each is necessarily limited, these chapters do serve well as an introduction to the whole field of pricing. Chapters are included on the mechanics and procedures of pricing, pricing problems and policies, pricing by primary producers and manufacturers, pricing by distributors, and price structures and the price system.

Marketing teachers will have mixed reactions to Part V, Interregional Marketing. While the material presented is important, of interest, and new to introductory marketing texts, the question arises whether it should appear therein in view of space limitations. Publishers apparently feel that textbooks of 700 to 800 pages are of "right" length. This imposes difficult problems of choice of materials upon authors. Furthermore, knowledge in this field of marketing has grown so tremendously in the past three or four decades that authors must, of necessity, give much attention to problems of inclusion and emphasis. Part V, to this reviewer, is marginal material for an introductory text, and it might well be condensed or reserved, in part at least, for advanced texts on marketing or for those on marketing research. If this material was condensed, more attention could be given to marketing history, to marketing institutions, to the marketing of agricultural products and raw materials, and to other subjects which are dealt with too briefly.

The final section, Part VI, Marketing Efficiency and Control, is well integrated and well related to other parts of the book. The authors discuss market research and information; budgeting and accounting controls; the social performance of marketing, with particular attention to the problem of measuring

efficiency; and government regulation To a greater extent than in Parts II and III attention sufficient to satisfy the reader has been given to each subject covered. The nature of the attacks on marketing and the defenses against them and questions relating to the social significance of marketing are particularly well handled.

Teachers will find this book more difficult to use than other marketing texts. For its effective use the instructor will have to be better prepared and more competent in the social sciences. The concepts are so erudite, the materials presented so condensed that the student will need more explanation and discussion in class sessions than is usually the case. While the book has a most interesting and challenging approach, it may be questioned whether some teachers of marketing are sufficiently well prepared to use it effectively. Furthermore, it deviates so much from the texts most commonly adopted that the instructor may have to reorient his thinking on marketing. Still the use of this book will provide a stimulating educational experience for both instructors and students.

It might also be noted that the content of advanced marketing courses may have to be changed if this introductory text is used. The reason is that the instructor can not assume to as great an extent as with other texts that the functions and practices of market intermediaries are known by students, or that they have a thorough groundwork in all phases of marketing, particularly from an institutional point of view. Nor does the book lend itself well to a joint case-textbook approach in a course.

The foregoing comments should not be taken as critical ones but only as a recognition of the fact that the authors have seen fit to prepare a different type of book than has customarily been written in this field. There is penetrating analysis in this book, there are many bits of wisdom sprinkled on its pages, there is good organization of subject matter and much good writing. Moreover, in general, collaboration among the authors has been effective. But whether such a book as this meets the requirements of a good introductory text unless the first course in marketing is postponed to the junior or senior year will be questioned by many marketing teachers. Few will doubt that the book should be required reading by students of economics and by those of business administration at some time during their college years.

D. M. PHELPS

University of Michigan

Industrial Organization; Public Regulation of Business

Defense, Controls and Inflation. Edited by AARON DIRECTOR. (Chicago: University of Chicago Press. 1952. Pp. x, 342. $3.50.)

In April 1951, the University of Chicago Law School sponsored a conference designed to "clarify the areas of agreement and disagreement" concerning economic controls during the post-Korea mobilization. Attending were 70

persons selected from business, law practice, journalism, labor organizations, legislative and administrative posts in government, and members of law and economics faculties. Working from a prepared agenda, separate sessions moved from monetary policy to fiscal policy, then to direct controls and on to the special problems Britain faces, and to the long-run effects of alternative control programs on free institutions. The verbatim report of the conference, introduced by a summary chapter by the chairman of the planning committee, constitutes the volume reviewed here.

From the opening session to footnote dissents to the one-chapter summary of the discussions, two sharply divergent policy programs were argued. One which was labelled that of the "Chicago School," consisted solely of vigorous monetary control carried out by Federal Reserve open market operations. No direct controls over wages, prices, or uses of materials, or over total amount or direction of use of investment funds should be imposed. Even a balanced budget, while helpful, would not be fundamental, for a deficit could be offset by still tighter money and the restricting effect of higher interest rates. Dissent from this extreme viewpoint was sharp and brought out an alternative program. The fundamental points of this plan were to place fiscal policy in the active rôle, with its effects reinforced by a marked, but not drastic, tightening of bank credit, and by varying degrees of direct control over investment and over the use and prices of scarce materials. Few argued for the general wage and price controls which were in force at the time.

These sharply different policy proposals are not new but the discussions of them provide an opportunity to reflect on the rôle of economists in one or more of the following steps in policy formation. (1) Clearly the economist is best qualified to provide, and is responsible for, the delineation of the underlying general relationship(s) in the area(s) of economics in which the problem falls. (2) Likewise, this reviewer contends, the economist must adapt such general theory, or blend it with other relevant theory, so as to develop the economic aspects of policy which the peculiar attributes of the particular problem require. (3) The further adaptation to what is legislatively and administratively feasible is the final step but one for which the economist has no particular competence. His counsel on probable economic consequences of alternatives may nevertheless be of value.

The proposal for sole reliance on interest rates as a mobilization period control does not go beyond step one. It is a literal application of the general doctrine that the price system is an efficient means for allocating resources. A business boom, a mobilization period, or full-fledged war all call for the same prescription. No attempt was made to show how, under the existing circumstances, resources would be reallocated with the speed and in the direction needed. Rather appeal was made to the logic of the price system, or how bad the alternatives are. On the specific point of whether interest rates could control inflation dissent was vigorous, but to criticisms of the plan the repeated response was in the vein of the poet's mountain climber, "Excelsior." Interest rates of 12 per cent would not bother Hayek (p. 59), for example. Such reasoning led Harrod to observe, "I should like to say that I do not think it is

an issue that can be decided by logic but rather by history and experience, and my contention is that history does not show that a tight credit policy can prevent the development of inflation in the kind of situation where there is a real demand for goods and services such as we have at the present time" (p. 64).

In like manner, but aimed directly at the logic of the "Chicago School's" position, was Hitch's observation that the theory which demonstrates the superiority of "free markets and the price system is a theory of 'comparative statics.' It shows that in a quite technical sense we can get an 'efficient' allocation of resources by using free markets in certain circumstances. But the method of analysis used is comparative statics. I know of no satisfactory theory which shows either that the path which the economy takes from one position of equilibrium to another is an optimal one or that, when time is important, we traverse that path at the optimal of speed" (p. 218).

Economists may debate whether existing theory gives insight into the character of the inter-equilibrium path, but that need not be resolved here, for it is speed and accuracy of readjustment of resource use which is fundamental. The risk of major errors cannot be taken for national security is involved. It was not economists at the conference who pointed out the irrelevance of Jewkes' argument that reconversion after the war in the United States and Germany showed how rapidly free markets could reallocate resources: Instead it was two lawyers and Senator O'Mahoney who indicated the fundamental difference between attracting resources temporarily from their long-term use, which is the mobilization problem, and releasing them to return to their long-term use, which is the reconversion process.

Equally important is the time pattern of developments during the mobilization period and the speed at which various controls can become effective, or cease to be necessary. That there had been the sudden impact of the Korean action, that there was under way a sharp buildup to a probably long-sustained higher plateau of military expenditures, got into the discussions only incidentally. What these facts meant for or against particular control programs or their duration does not stand out in the proceedings.

That the discussions did not deal systematically with such topics reflects the fact that the conference did not start with a consideration of the unique aspects of the mobilization problem. Had this been done, attention would have focussed quickly on step two mentioned above. That this was not done indicates once more the viewpoint of those who prepared the agenda for they are of the "Chicago School." To them mobilization is not or should not be dealt with as a unique problem. That is the logic of their position, although that logic is reinforced by step three considerations to the effect that controls may damage the free market system permanently.

Proponents of the composite program, which would include at least some direct controls, also had their views of political desirability. These included political inacceptability of very tight money and of falling prices and wages in sectors of the economy from which demand shifted. Consequently the monetary program would be ineffective and inflation substantial and real damage would be done to free institutions.

In noting the position taken by participating economists, one finds a fairly high, but not perfect, correlation between the extent to which individuals had been involved in public policy formulation and the program they supported. In general those who had had active rôles in World War II or Post-Korea mobilization, or had participated in the policy studies by such groups as the Committee for Economic Development or the RAND Corporation, favored the composite program which included at least some use of direct controls. Does the view of economists in these positions reflect a bending to political expediency, or a greater awareness of the unique problems of a mobilization period? Or do those who adhere to monetary policy only, or even that plus active fiscal policy, understand the economics of the situation more clearly; or are they blind to essential conditions? The reviewer frankly is of the former school and suggests that the "discipline of responsibility" aids in the formulation of, but should not dominate, economists' views on policy. When the lay participants in the conference referred to the "highly abstract" character of much of the discussion, this was their way of asserting that the proponents of the exclusive use of tight money had not adapted their analysis of the market system to the facts and forces of a mobilization period.

RICHARD B. HEFLEBOWER

Northwestern University

Grössenordnung und horizontale Verflechtung in der Eisen- und Stahlindustrie der Vereinigten Staaten, Grossbritaniens, Frankreichs, Belgiens, Luxemburgs und Deutschlands. By HERBERT STEINER. (Kiel: Institut für Weltwirtschaft, Universität Kiel. 1952. Pp. v, 119.)

This very well documented publication investigates the relative size and horizontal integration of the iron and steel industry of the six countries mentioned in the title of the book. The relative size of the firms is measured in two ways: first by comparing the volume of output, and second by comparing the amount of capital investment. The relatively greatest concentration of economic power is found in Luxemburg where in 1950 the leading concern (ARBED)produced 64.5% of the raw steel. Next in line was Germany (Vereinigte Stahlswerke, 38.7% for 1938), the United States (U.S. Steel Corporation, 32.5%), Belgium (group Cockerill, 32.1%), France (group de Wendel, 19.5%) and Great Britain (United Steel Cos., 13.1%). The schedule of capital investment does not completely parallel the above sequence. In France and Great Britain the top producers are not the ones with the largest capital investment.

Much more interesting than the above, purely statistical, survey is the part of the publication dealing with horizontal integration. Here, the author shows the basic difference between industrial organization in the United States and in the European countries. The concentration and growth of heavy industry in the former has taken the form of holding companies (U.S. Steel and Bethlehem Steel) or outright mergers (Republic Steel) rather than of loosely organized concerns based on mutual shareownership and interlocking directorates customary in Europe.

Unfortunately the author gives us no information at all of the horizontal integration in Germany prior to May 1, 1952, the date on which the disintegration of German heavy industry by order of the Ruhr Authority was completed; nor does he draw any conclusions concerning the effects of horizontal integration on output and price formation.

Atomic Power—An Economic and Social Analysis. A Study in Industrial Location and Regional Economic Development. By WALTER ISARD and VINCENT WHITNEY. (New York: Blakiston. 1952. Pp. xi, 235. $4.75.)

Highly significant public policy issues may arise during this session of the Congress as the nation's legislators seek to clear the statutory way for future industrial development of electric energy from nuclear sources. Looking beyond these domestic policy problems, Isard, an economist, and Whitney, a sociologist, have joined forces in a successful interdisciplinary effort to analyze the more distant influence of nuclear power upon the location of large fuel- and energy-consuming industries and upon the development of industrially developed and undeveloped economies. The study follows by a year and a half the rather similar one prepared, under the direction of S. H. Schurr and J. Marschak, by the Cowles Commission.[1] Both are useful preliminary explorations into uncharted territory, that alluded to in Section 7(b) of the Atomic Energy Act of 1946. This directs the U. S. Atomic Energy Commission and the President to submit to the Congress a report, with legislative recommendations, setting forth their "estimate of the social, political, economic, and international effects" when the industrial, commercial, or other nonmilitary use of atomic energy has been "sufficiently developed to be of practical value."

The Cowles Commission study made rather optimistic assumptions concerning the future cost of nuclear power, but after surveying a number of large fuel- and power-consuming industries found that the probability of substantial savings in cost appeared small, although locational shifts might be facilitated by nuclear power in special circumstances. The findings of Isard and Whitney are not essentially different, although the method of analysis diverges in certain essential aspects, to be mentioned later.

At this stage of our knowledge Isard and Whitney are compelled to speculate on, rather than to measure, the expected impact of future nuclear power utilization. They first review the open literature on reactor technology (Part I) although the point of doing so is hardly made clear in economic terms. While recognizing that military needs during a long period of international tension are likely also to promote technical progress for peaceful applications, they

[1] *Economic Aspects of Atomic Power.* An Exploratory Study Under the Direction of Sam H. Schurr and Jacob Marschak (Princeton, 1950). Reviewed in this journal, December 1950, XLI, 994-95.

fail to appreciate the significance of possible dual-purpose nuclear reactors, producing as joint products power and fissionable material. After reviewing (in Part II) the scanty literature available on estimated nuclear power costs, practically all of it enthusiastically inspired during the first year after Hiroshima, Isard and Whitney take a skeptical attitude toward *specific* unit cost estimates, notably those of Schurr and Marschak, derived from the so-called Thomas report (1946). They quite properly conclude that no one can yet "really predict even a meaningful range of costs of atomic power at future stages of development" (p. 25). They prefer instead to think in terms of the levels to which nuclear power costs must fall to affect production costs, location of industry, or the introduction of new processes. The weakness of the specific cost approach can be readily demonstrated. If the cost of electric power from nuclear sources is dependent in part upon the "price" of byproduct fissionable material, then the specific cost of electric power becomes indeterminate.

The direct cost-saving effects of nuclear power, Isard and Whitney proceed to show, are likely to be small, noting that purchased energy and power for United States manufacturing industries have never exceeded 7 per cent of the value added by manufacture. They look momentarily at possible indirect effects, concluding that Leontief's input-output analysis of interindustry relations may hold some hope of providing a method of measurement. After analyzing the theory of industry location, the authors state that "any lowering of power costs based on nuclear energy will hardly be of sufficient importance to nullify other locational forces. Any wholesale relocation of industry is unlikely" (p. 71). Case studies are made of the cement, glass, iron and steel, and aluminum industries.

In Part III the authors assess the impact of nuclear power upon economic development and upon regional economies, recognizing the contributions of such sociologists as W. F. Ogburn, H. Hart, and S. C. Gilfillan, who have stressed the cultural factors impeding or facilitating technological innovations. Isard and Whitney find that utilization of nuclear power, as for other innovations, will be determined by the conflict between "cultural resistances" and the effective need for low cost power. Thus, in industrially undeveloped nations cultural resistances and lack of real demand for energy resources may combine with the shortage of capital and skilled personnel to prevent significant utilization of nuclear power. An interesting case study is made of Brazil, an essentially agricultural economy deficient in both petroleum and coal. Power, they conclude, is unlikely to be the key to the economic growth of such industrially undeveloped nations.

Turning to industrialized areas, the authors suggest that the "stage of industrialization" may greatly influence the contribution of nuclear power but the brief for this seems hardly convincing. There is no disputing the fact, however, that while mature economies may possess requisite capital and technical resources, perhaps the controlling factor will be the extent to which aggressive industrial leadership, possibly assisted by government, will feel impelled to undertake nuclear power development. After comparative study of a number of highly industrialized countries, Isard and Whitney somberly conclude that

"among major nations, the United States appears least likely to improve its *relative* economic status through atomic development" (p. 187). Their final conclusions are realistically restrained. They foresee major cost savings as unlikely, and expect only limited commercial use of nuclear power. They concede that there may arise new industrial processes and a host of indirect effects not now discernible. This study is not the last word on a speculative subject, and the authors would be the last to suggest that it is.

Having benefited by two useful exploratory investigations, economists may now well ask, "How should we, and other social scientists, usefully proceed to analyze the advent of nuclear power?" Enumeration of the topics both studies failed to explore may be helpful. First, neither study assayed what small savings in power-generating costs might mean to the electric utility industry as such, having considered electric power consuming industries only. It is in the electric utility industry that nuclear power must make its economic way. Second, both studies were preoccupied with conventional industrial applications of relatively low cost electric power, and avoided consideration of specialized applications where nuclear power, because of its special technical characteristics, may be a peculiarly attractive and economical alternative. Nuclear power plants may ultimately have special advantages either as small "package" plants (for use in isolated areas, in ships and cargo planes) or as large complexes, exceeding 1,000,000-kilowatt capacity, located in high cost areas of heavy consumption. Third, one would hope that a careful analysis will be made of the nation's long-term need for nuclear power weighed against the vast conventional energy resources likely to be available over the next half century, but with rising fuel costs pushing electric power rates higher. Does industrial nuclear power on economic grounds warrant a major national effort? Finally, and most important perhaps, it is about time that economists and other social scientists began to direct special attention to the immediate issues of national economic policy impinging on the introduction of nuclear power for industrial purposes.

The U. S. Atomic Energy Commission recently announced that four industrial groups had submitted comparatively optimistic interim reports on the industrial development of dual-purpose power reactors. Such reactors were said to be technically feasible; the problems remaining are essentially economic and political. Should it prove possible to declassify these reports for public use, economists will have available for the first time technical and economic data needed for fruitful analysis of long-range implications, as well as imminent economic problems.

Here are some of the notable issues appearing, as the present provisions of the Atomic Energy Act of 1946 become impaled on the emerging facts of industrial nuclear power development: government monopoly is provided in the Act; should a new public policy be established permitting private ownership of nuclear power plants? How can the development of nuclear power be made consistent with the overriding requirements of the national defense? Should fissionable material needed to fuel civilian reactors be diverted from military uses? Should the federal government guarantee a long-run market for industry-produced plutonium? What rôle should such federal agencies as the TVA

and the Department of the Interior play in the industrial development of nuclear power? These and many other questions are now arising to challenge economic analysis in the formulation of public policy.

Transportation: Principles and Problems. By T. C. BIGHAM and M. J. ROBERTS. 2nd ed. (New York: McGraw-Hill. 1952. Pp. xvi, 710. $6.00.)

The present volume, which is a revision and enlargement of a well-known text on transportation, is similar in scope to other texts in this field, but, as might be expected, differs in emphasis and organization. Since it is of moderate length and somewhat shorter than its leading competitors, some topics inevitably are treated very briefly. Opinion will doubtless differ widely as to the wisdom of the authors' allocation of the available space. The reviewer's opinion is that most subjects receive adequate attention and that in general the present volume is an improvement over the first edition. The most significant improvement, in his view, is the addition of chapters entitled "Transportation and Production" and "Transportation and Exchange." These cover the important subjects of the effect of freight rates on the location of industry and the relation of freight rates to the prices of commodities.

On the other hand, the reviewer feels that somewhat fuller treatment of a few topics would have been desirable. One such topic is transportation cost, which is good as far as it goes but which might well have included some discussion of empirical studies of cost, such as the rail and motor cost studies prepared by the staff of the Interstate Commerce Commission. A second topic which, in the reviewer's opinion, deserves somewhat more space than the nine pages allotted to it in this volume is public policy with respect to control over entry, especially as regards motor and air transportation. Third, the legal obligation of carriers with respect to such matters as acceptance of shipments, supply of equipment and liability for loss and damage would seem to merit at least a substantial portion of a chapter, whereas only about one and one-half pages are devoted to them. Finally, one other general topic which might well have warranted further attention is the organization and procedure of the federal transportation regulatory agencies, proposals for the reorganization of these agencies, and the relation of regulatory agencies to the courts and to the executive branch of the government. In contrast more than half of the chapter on the general level of rates (32 out of 58 pages) is devoted to the question of valuation and rate of return, an allocation of space which seems somewhat excessive in view of the relatively subordinate rôle played by these matters in discussions of transportation policy at the present time.

The general plan of organization of this volume is to treat successive topics "across the board" with reference to each agency of transportation instead of giving a complete treatment of each agency of transportation in turn. The reviewer expresses no opinion as to the respective merits of these two general

approaches but he would recommend at least two changes in the organization of individual topics. One of these is in connection with the treatment of transportation cost. Chapter 6, entitled "Transportation Costs: Economic Basis of Rates and Regulation," discusses constant and variable cost, common and separable cost, discrimination and ruinous competition; while Chapter 12, entitled "Principles Underlying Particular Rates," considers the economies of full utilization, long-run decreasing cost and value of service. The purpose of the authors in thus separating the treatment of these topics is apparently to make Chapter 12 serve as an introduction to the succeeding chapters on rate structures and the control of discrimination. The reviewer is of the opinion, however, that considering the close interrelationship of the topics mentioned there would have been a clear advantage in treating them together in the earlier chapter.

The reviewer's other principal comment with regard to the organization of the volume is that a more unified treatment of the problem of transport coordination would have been desirable. The volume contains much good material on this subject, notably in the chapter on interagency rate relations, but it might be difficult for students to obtain a comprehensive view of the various aspects of this intricate problem because the various aspects are not drawn together and related to one another in a single chapter or series of chapters.

The authors' views regarding transportation policy are conveniently summarized in the concluding chapter. Among other things they recommend that the declaration of national transportation policy in the Interstate Commerce Act be broadened to embrace promotion as well as regulation and to include air transportation in addition to the agencies presently covered. They favor centralizing regulatory authority over all forms of transportation in the Interstate Commerce Commission, maintaining the status of the Commission as an independent agency, and centralizing promotional functions in a Department of Transportation or in a division of the Department of Commerce. They present in some detail recommendations for the relaxation or liberalizing of regulation in some directions and for the extension of the scope of regulatory authority in others.

With a few changes in the order of assignment of chapters along the lines suggested above, and with the introduction of supplementary material at a few points, the reviewer believes that this volume should prove to be a satisfactory text for a general survey course in transportation.

ROBERT W. HARBESON

University of Illinois

Economics of Transportation. By RUSSELL E. WESTMEYER. (New York: Prentice-Hall. 1952. Pp. viii, 741. $6.00.)

A writer of a text in transport economics must necessarily select an emphasis, for the volume of material and problems to be described and analyzed in the field is too large to permit complete treatment. In his approach, Professor

Westmeyer has emphasized the public utility characteristics of transportation and the railroads among the major agencies. Thus, the text will appeal most to those who desire to give primary attention to the history and development of regulation and to railroad problems. Notwithstanding, considerable discussion is found of problems in air, motor and water transport, although subsidy and its effects upon the railroads receive the most thorough analysis; and some problems, such as the economics of highway investment, are scarcely mentioned. Freight forwarding, railway express, parcel post and Pullman services are discussed briefly, but many will regret elimination of reference to international shipping, the rôle of the automobile, and intracity transport.

The text is somewhat long for a one-semester course in transport economics, but with supplementary readings in periodicals and monographs, it could additionally be used in a transport problems course. It is readable and the exposition is clear. The author desirably avoids use of too many details of interest only to technicians and offers students the aid of numerous background explanations. The general tone is objective. Many economic problems are raised for discussion, with little tendency to express definitive judgments. Two methodological features open to criticism are the slight use of maps and charts showing facilities, traffic flows and the relation of rates to distance, and the infrequent reference to the best periodical literature. While other texts are cited frequently as suggested readings, the limited references supplied will not stimulate inquiring students to read more thoroughly in the appropriate theoretical works and in special monographs. However, helpful footnote references to leading regulatory decisions are found in chapters on regulation.

As with most transport texts, this one is heavily descriptive with respect to transport development, regulation, and rates and services. Although general statements of the nature of the transport market as a whole, the incidence of freight rate changes, the theory of transport demand, and the theory of rates are not found, much pertinent analytical comment appears throughout the book in reference to particular problems. Such analysis is usually clear-cut and competent. Nevertheless, many readers will regret the lack of a unifying frame of reference. As one proceeds through the chapters to the final two devoted to general transport problems and policies, one becomes increasingly aware that the author is concerned with an economic allocation of resources in transport. Yet Westmeyer does not inform the reader of that dominant theme at the beginning, nor does he comprehensively develop the theory and requirements of economic allocation. Much of what disturbs him about the resource allocation depends upon his assumptions of a normal oversupply of transportation, excess capacity in the railroad industry, and a high ratio of constant costs in that field. The economies of utilization and highly variable profitability in railroading are frequently mentioned in calling attention to the pessimistic consequences to the railroads and the public of the growth of other agencies relative to the railroads; of development of facilities in each agency independent of the effect upon other agencies; of the opportunity to operate which is granted to limited common carriers and to contract, private and exempt carriers; and of the excess transport supply resulting from subsidies to air and water trans-

port. And while the criterion of the position of the railroads is applied throughout, far less attention is given to the benefits of technological and service innovation, the advantages of reasonable excess capacity, the relation of transport to economic development, and the economics of investment. Does Westmeyer think a repetition of the restrictive tendencies of the 1930's in transport regulatory policy desirable? Some transport economists thought that the last war had ended the myopia of depression years in regard to adjustment of supply to demand!

Since transport economics basically must be concerned with allocation of resources, any text must examine the economic effects of promotional and regulatory policies upon the railroads. Those concerned with wastes in transport and continued private ownership of railroads will heartily endorse Westmeyer's frequent reference to evidence of the wasteful effect of subsidized transport. Admittedly, removal of subsidies would improve the allocation of resources, although Westmeyer appears at several points to exaggerate the benefits to railroads. But aside from measures to reduce subsidy, it is not shown how further coordination, which is described in confident and glowing terms, can be accomplished. Coordination is a nice word but its real possibilities cannot be developed without serious consideration of advantages of uncoördinated transport where subsidy has been removed and without close analysis of the workability of competition in transport. Neither is treated adequately in the book. The disbenefits of further control of interagency competition, a policy strongly implied, must be realistically appraised, not just mentioned and glossed over. And it is questionable that economic coordination can be evaluated solely in terms of high constant costs in railroading.

Despite the text's concentration upon regulation in each transport field and substantial exposition of regulatory policies, little attempt is made to develop comprehensively the economic results, positive or negative, which regulation and regulatory agencies have accomplished for the public. This is a common fault of most transport texts. Since transport functions through regulated markets, there appears an uncritical tendency to accept the regulatory structure and merely to describe key policies. While this may be informative, Westmeyer's statement of accomplishments of regulation in terms of the number of application and other cases which the Interstate Commerce Commission and the Civil Aeronautics Board have successfully handled is not very meaningful. It is not the process of regulation which is ultimately important, but whether it does, in fact, stimulate investment, innovation and invention; improve the allocation of resources; and work towards lower real costs. However, Westmeyer can be commended for drawing attention to some particular regulatory policies, such as certificate restrictions, which merit examination from the standpoint of end results.

The text is teachable and a useful addition to the growing alternatives available to those who offer courses in transport.

Washington State College

Industry Studies

Competition in the Rayon Industry. By JESSE W. MARKHAM. (Cambridge: Harvard University Press. 1952. Pp. xvii, 245. $5.00.)

Professor Markham's analytical study is a useful addition to the literature of industrial organization and behavior. The principal sources of his factual information were the trade journals and Federal Trade Commission hearings, but the author has also had personal experience in the industry and has enjoyed the cooperation of some of its members in estimating the relationships between cost and size. He successfully explains the structure of the industry and its behavior in terms of its underlying technology and of its historical and institutional background and then proceeds to evaluate its performance according to criteria of competitive workability.

The rayon industry in the United States dates from the establishment of the American Viscose Corporation as a subsidiary of Courtaulds, Ltd. in 1910. Patent protection and requirements for technological "know how," even in the absence of patents, acted as barriers to entry and limited success in the early years to subsidiaries of established European producers or to companies which could secure their help. The rayon industry thus was highly concentrated from the start, and marked cost advantages to size have kept the number of firms small. There are now 16 firms, 4 of which do 75 per cent of the business.

The products of all firms are identical grade for grade which suggests that in a concentrated market, price tactics must be either cutthroat or cooperative. Among other influences, common historical links to members of the European rayon cartel have encouraged cooperation. Cooperation has been achieved through price leadership, which Markham identifies with Stigler's "dominant firm" and "barometric" types, and through outright collusion on at least one occasion.

The cooperative interest in price is restrained, however, by two other market factors: the competition of other fibres and a strong incentive on the part of each firm to maintain capacity production. With technological progress rayon fibre has become an increasingly close substitute for other fibres in an increasing number of uses, with a consequently high cross elasticity of demand. The industry also believes that stable rayon prices are attractive to the fibre-using branches of the textile industry. Thus competition of other fibres both limits the level of rayon prices and encourages their stability.

The limit to the level of prices is reinforced and the stability of prices is threatened by the interest of each producer in capacity production. Each plant at any point in time has an inflexible upper limit to output while unit and marginal costs rise if output is curtailed below this level. Seventy-five per cent of capacity is a critical level below which costs rise sharply. Thus if sales decline, production is maintained for a time and inventories rise. With a prolonged decline, output must be cut and costs rise. The smaller firms, owing to higher cost levels, are most seriously affected, and if the cut is severe, they are likely to shade prices in secret while list prices, which usually are the actual prices, remain identical for all producers. If output is curtailed more

than 25 per cent the price leader is likely to reduce list prices thus reestablishing uniformity and enabling rayon to compete with other fibres on better terms. In this way a cooperative solution is found to the conflicting aims of price stability and capacity operation under conditions of fluctuating and highly elastic demand.

The net results of this market pattern have been rapidly changing technology, rapidly growing production and steadily falling price. In the early days when rayon producers had an effective monopoly of an inferior product with few close substitutes, the profit rate was high. By the late 1930's with a vastly improved product competing closely with other fibres over which rayon producers had little control, the profit rate on investment was no higher than the average for manufacturing corporations. There is little evidence either of output restriction or of price rigidity at the expense of output.

Markham concludes that the industry is workably competitive and suggests no revision of its structure. He observes that rayon has enjoyed a sheltered market as a result of absolute tariff protection since 1930 and as a result of the support given to cotton prices by the agricultural programs. The gradual removal of tariff protection is suggested.

This reviewer finds little reason to differ with Markham's analysis of the industry on any important issue. My principal complaint is against a generally awkward organization. As one example, Chart 11 which is first discussed on page 49 does not appear until page 150. To some extent this type of thing is a matter of personal taste and at the most detracts from the pleasure and ease of reading. It does not prevent this from being a good, convincing and enlightening book.

RICHARD B. TENNANT

New Haven, Connecticut

Land Economics; Agricultural Economics; Economic Geography

Resources for Freedom. VOL. I: *Foundations for Growth and Security.* VOL. II: *The Outlook for Key Commodities.* VOL. III: *The Outlook for Energy Sources.* VOL. IV: *The Promise of Technology.* VOL. V: *Selected Reports to the Commission.* A Report to the President by the President's Materials Policy Commission. (Washington: Supt. Docs. 1952. Pp. viii, 184; x, 210; viii, 43; x, 228; x, 154. $1.25; $1.50; 50¢; $1.75; $1.25.)

As economics has grown in scope and complexity, economists have begun to search for a single unifying concept around which to organize the massive collection of factual data and analytical tools which the student of economics is expected to master. Such attempts have failed so far, as in the brief vogue of consumer economics a few years ago, but the search by no means has been abandoned. Neverthless, if success should be achieved it may not be the result of direct search but may well come through serendipity.

Certainly, the President's Materials Policy Commission did not set out to look for a unifying concept for economics, even though a study of its five-

volume report leads one to conclude that it may have taken a long step toward finding it. The Commission was charged with the responsibility of attempting to discover how large a supply of materials would be required by the American economy in the future and whether such materials would be forthcoming. In its attempt to answer these questions, the Commission undertook to examine the growth potential of the national economies of the "free world," and in particular to project the growth of the American economy to 1975. This emphasis on economic expansion is so consistently present and so well related to the discussion of various economic problems associated with the procurement of materials that it emerges as the central theme of the Report. Indeed, the handling of the growth concept is so skillful as to suggest the possibility of a general reorientation and integration of the diverse, specialized fields of economics around this single unifying concept. For the Commission's study of the materials problem has led it into virually every field of economic inquiry and has resulted in a document which contains something of interest and significance for many more economists than those whose primary interest is in the field of resourses utilization.

Price economics is represented in at least three forms. First, there is the insistence of the Commission that "nothing should be permitted to interfere with the principle that materials should be obtained at the least possible cost for equivalent values" (Vol. 1, p. 20), and its equal insistence on the fundamental importance of real cost as distinguished from money cost. Second, the Commission emphasizes the institutional character of the price-making process and examines these interferences with the processes of price determination which tend to hinder the development of a given resource, encourage its wasteful use, or discourage the introduction of substitute materials in the face of growing scarcity. Third, the Commission discusses the nature of cyclical price instability in the world markets for raw materials and relates these instabilities to the problems faced by the American economy in assuring itself of a steady and uninterrupted supply of essential materials, both for economic growth and for national security.

In the field of international trade the Commission examines the effects on materials acquisition of the multitudinous barriers to trade which exist in the world today. It discusses the possibilities of private and public investment in foreign countries as a means of securing for this country adequate supplies of needed or essential raw materials. In line with its emphasis on growth factors the Commission pays particular attention to the problems of economic expansion in the so-called underdeveloped areas of the world. In line with its necessary concern with problems of national security and defense, the Commission discusses the military strategy of raw materials supply; and in doing so divides the world into two groups—the "free, non-communist world" and the communist group of national states. Both in its appraisal of the present world situation and in its recommendations for policy this Report offers substantial contributions to the economics of international trade.

There are, of course, sources of controversy in this part of the Report. If the projections of materials consumption for the United States and for the rest of

the "free world" are taken as forecasts they can only be challenged on technical grounds, but if they are interpreted as guides to policy a question immediately arises. For a policy based on these projections would seem to claim a lion's share of future output of many materials for the United States, while failing to allow for adequate aggregate expansion elsewhere. Some of the friendly nations are likely to describe this attitude as "economic imperialism," thinly disguised for the American reader by the Commission's justification of such policies by the principle of "enlightened self-interest."

On the other hand, the Commission does refuse to approve private or public policies of procuring our raw materials from the underdeveloped countries by the overt methods of colonial exploitation. Instead it cites with approval (and in Vol. V describes at some length) the policy of Venezuela which uses the revenues from the development of that country's petroleum resources to promote the education, social services and industrial progress of the Venezuelan people.

Turning to a third field of economics, it may be noted that the Commission attacks boldly and at length the delicate problems which arise in the general area of social control and economic planning. At the outset the Commission states that its members

> believe in private enterprise as the most efficacious way of performing industrial tasks in the United States. With this belief, a belief in the spur of the profit motive and what is called "the price system" obviously goes hand in hand (Vol. I, p. 3).

They further state that:

> We believe in a minimum of interference with these patterns of private enterprise. But to believe in a minimum of interference is not to believe that this minimum must be set at zero. Private enterprise itself has from time to time asked for helps, or restraints, or counterpoises from Government to keep the system working at its best; for this reason, among others, we have experienced for a long time a mixture of private and public influences on the functioning of our economy. The Commission sees no reason either to blink this fact or to decry it; as we see the future, the co-existence of great private and public strength is not only desirable but essential to our preservation (Vol. I, p. 3).

Probably there will be little disagreement with these propositions as a statement of principle. The rub comes when one attempts to define precisely what is included in, and excluded from, "a minimum interference with private enterprise." Throughout the Report there is a struggle with just such an attempt at definition. In Chapter 5 the Commission states the basis of its own policy recommendations as follows:

> The task of overcoming the materials problem is far greater than merely locating enough physical resources. The task is to overcome the multitudinous barriers described in the last chapter, but, more than that, to offer positive spurs and encouragements for developing and applying energy and technology to the materials field, for insuring a sufficient flow of capi-

> tal into it, for guarding our security, and concerning ourselves at every point with insurance against rising costs (Vol. I, p. 17).

Having set its goals the Commission then recognizes the impossibility of achieving them without a program of economic planning, saying that:

> Such a set of accomplishments will never be achieved at random: only a consistent policy toward materials can hope to bring them about. Policy means here intelligently directed action toward consciously determined goals—as distinct from aimless drift and blind faith. It is not enough to solve the problem "eventually"; while the Nation waits it can encounter such a succession of individual shortages as to disrupt the cost pattern and defeat an "eventual" solution altogether (*Ibid.*).

The Commission then deals with the problems of materials supply assigned to it by the President by setting forth in Volume I some seventy-eight separate recommendations, most of which are specific and technical in nature and nearly all of which require government action. In addition, the Commission states its conclusions or beliefs on a larger number of other points which involve implications for policy decisions. These recommendations and suggestions for private and public policy are justified as being attempts to minimize interference with the least-cost principle as applied to the utilization of resources in the process of production and trade. Equally, the Commission's emphasis on real costs makes it possible to interpret the least-cost principle as dealing primarily with marginal social costs rather than with marginal private costs.

Many economists will agree with the Commission's philosophy, but professional and entrepreneurial opinions concerning the specific recommendations are likely to vary widely, partly for technical reasons, but also because of doubts whether the Commission's recommendations can be implemented without doing violence to the Commission's own belief "that the bulk of the task of insuring adequate future materials supply can best be carried out by private business under the competitive market structure, operating within broad policy outlines which it is the responsibility of the Government to provide" (Vol. I, p. 17). But whatever one's opinion on this issue it must be agreed that the Commission in dealing with the problem of the functions of advance planning and with the rôle of government in the contemporary economic affairs of the United States so directly and explicitly, has made a substantial contribution to present-day political economy. By the same token, it also has contributed to our understanding of the institutional aspects of economic growth.

The above discussion has dealt with what might be called the by-products of the Commission's primary task. Viewed as a statement of the problems of resources utilization for the next quarter-century the Report is worthy of very high commendation. It is almost the first government report on resources to emphasize the economic and administrative aspects of resources development rather than the physical. It is, in effect, an elegant and massive superstructure built on the foundations provided by Zimmermann and Dewhurst; although there are, quite naturally, many unfinished and unfurnished rooms in the edi-

fice.[1] The Report contains studies and reports on dozens of raw materials and examines in separate volumes the future outlook for key commodities (Vol. II), and for sources of energy (Vol. III). In Volume IV most of these commodities are re-examined in terms of the promise of future technological change. Volume V completes the Report with a series of supplementary studies selected from the large number prepared for the Commission. Although the Report gives consideration to virtually all materials, its discussion of problems of soil and water utilization is brief, and recommendations in these fields (except for industrial water supply) are left to other agencies.

No review could summarize or criticize adequately the many aspects of this Report. The Commission's recognition of the rôle of technology in our society, and of our failure to make the most of the promise of technology or even to train enough technologists is very important. Equally significant is the emphasis upon the need for further research in many directions—economic, administrative, and social as well as in the areas of the physical sciences. The presentation in a public document of the projections to 1975 of population, Gross National Product, and disposable income in the United States is even more exciting. Such projections provide the essential base for any realistic discussion of the problems involved, and of the policies required to assure the nation of adequate supplies of materials in the future. Nothing could bring home better to economists or to laymen the great promise of the future, or the reality of the problems to be solved if this promise is to be realized. For as the Commission itself observes:

> The five volumes of this Commission's Report are offered only as a beginning. The most important conclusion this Commission presents is thus that the job (of assuring materials supplies) must be carried on cooperatively by Government and private citizens, not periodically at wide-spread intervals, but day by day and year by year.

The ultimate influence of the President's Materials Policy Commission will depend upon how well the entrepreneurs of the American economy, both private and public, take heed of this conclusion.

Housing Market Behavior In A Declining Area. By LEO GREBLER. Publication of the Institute For Urban Land Use and Housing Studies. (New York: Columbia University Press. 1952. Pp. vii, 265. $4.50.)

Dr. Grebler's book is the first of a projected series of studies in the behavior of urban housing markets undertaken by the Institute for Urban Land Use and Housing Studies of Columbia University. The Institute is under the able leadership of Dr. Ernest M. Fisher, universally recognized as a pioneer in the scientific investigation of these fields.

[1] *World Resources and Industries* (Rev. ed.), by Erich W. Zimmermann, (New York, Harper and Brothers, 1951). *America's Needs and Resources*, by J. Frederic Dewhurst and Assoc. (New York, The Twentieth Century Fund, 1947).

Through the intensive application of some known research methods and the development of some new and ingenious series, Grebler has succeeded in tracing the history of New York City's Lower East Side over a fifty-year period beginning in about 1900. His is not merely a general descriptive history, but much more importantly, an attempt to analyze market behavior in historical terms, to separate cause and effect, to identify and interpret the interaction of forces. Probably the most significant contribution of the book, however, is in fulfillment of one of its stated objectives, namely, to identify the materials and techniques required for the study of market behavior. It is to be hoped that another of the objectives will be realized: "to stimulate a number of local studies in various cities, which in the aggregate should make it possible to arrive at both generalizations and differentiations in respect to market behavior at the bottom end of the housing supply."

This is an exciting and stimulating book for students in the field, and these words are used advisedly, because they can but rarely be applied to research studies. While this reviewer could hardly be said to have read the book breathlessly he did have his interest held throughout, even while examining the charts and tables and the appendices, and even while reading Grebler's carefully expressed limitations upon a generalization of his findings based upon this single exploration. The absorption with which the book is read is not only a tribute to the material, its logical organization and unusually good writing but very significantly, to the fact that the reader, probably for the first time in his experience, is provided an almost complete set of data on real estate market phenomena and the interpretations of a capable analyst with which he can agree or disagree.

While recognizing the signal contribution of this book, both as an investigation and as a prototype for other studies, it was impossible to be free of the nagging feeling that the Lower East Side is an extremely atypical area and New York City is perhaps the most atypical of American cities. It was even somewhat difficult at first to accept this as a declining area in the general use of the term. This was an area which was originally built with relatively low grade housing many years before 1900. Even today, about 70 per cent of residential units, exclusive of public housing, are in "old-law tenements" (p. 121), which means units built before 1901. Furthermore, Grebler reports (p. 120) that during the last half of the nineteenth century and at the beginning of this century there is ample evidence that the quarters on the Lower East Side were below accepted standards, and (p. 6) that much of the area was considered by the community-at-large to be detrimental to health, safety, and welfare.

The case is made that this area in 1902 had an average rental not much below that for other areas in Manhattan. The normal implication of comparable rents is comparable quality. Grebler explains (p. 121) that the small differential in rents was probably due in part to "the almost compulsory factors which at that time caused immigrants, without knowledge of English and of ways of 'getting around' in a foreign country, to crowd into the area." The clear implication of this is that at the time the study begins in 1900, but for abnormal demand factors, there probably would have already been a wide

rental differential between the Lower East Side and the remainder of Manhattan.

It is evident that since 1900 the area has declined relative to the rest of Manhattan. The question arises: would the relative decline have been so great but for the fact that at the beginning of the period rents were held at a high level by unusual circumstances? Probably too much emphasis has been put upon this as a declining area. The purpose of the analysis would have been equally met—and the contribution certainly no less—if the study had been cast in the framework of market behavior over time in an area which was relatively low grade to begin with. In fact even less attention has been paid to the latter than to the decline of fashionable or upper-class neighborhoods.

After an excellent summary of present thought on the "filtering down" process, Grebler suggests that probably the best measure of "filtering" is the change in position of a dwelling unit or group of dwelling units in the distribution of rents and prices in the community as a whole. Unquestionably this measurement is a very useful one in analyses of market behavior. It does not appear, however, to measure the phenomenon that economists for a long while have described as the "filtering down" process, as defined for example, by Ratcliff (cited by Grebler, p. 56). It is difficult to see how the concept stated by Ratcliff, and generally accepted, can be subjected to measurement without data on both the incomes of occupants and the rentals or prices of the units. The reader is somewhat puzzled (pp. 61, 62) as to whether Grebler disagrees with the generally accepted concept of "filtration" or concludes pragmatically that the empirical data necessary to its testing cannot be assembled. He does not in any event make the case that his is a better or more rational measurement of the same phenomenon.

While much of this review has been used for raising questions about Grebler's book, to have said all the good things about it would have taken infinitely more space. This book is a major contribution and marks a significant advance in the understanding of both the data required and the concepts involved in analyses of market behavior. It is highly important for Grebler, and the Columbia Institute, to push on.

LAWRENCE N. BLOOMBERG

Washington, D.C.

Labor

The Impact of the Union. Edited by DAVID MCCORD WRIGHT. (New York: Harcourt, Brace. 1951. Pp. ix, 405. $4.00; text edition, $3.00.)

This volume seems to have developed from a feeling that—to paraphrase a famous remark about generals—labor economics is too important to be left to the labor economists. This reviewer, who tries to be friends with theorists, labor economists, and union officials, can only feel that a dirty trick was played in asking him to write this review; and he hopes that he may have a few friends left after the review has been written and read.

It is undoubtedly true that wage theory cannot be handled most effectively

as a specialty, but must be treated in context as part of a larger apparatus of analysis. A revival of interest in wages by general economic theorists is long overdue and much to be desired. This volume, the most provocative group of essays about wages which has appeared in recent years, suggests that such a revival may be in the making.

The volume includes papers by Professors Clark, Haberler, Knight, Boulding, Chamberlin, Friedman, Samuelson, and Wright. The papers were written for and discussed at a conference sponsored by the American University. Most of the round-table discussion of the papers by the eight participants has been included in the volume, forming about one-third of the total text. The discussion is interesting and helps to bring out the distinctive flavor of each man's thought.

Despite the effort at integration through a conference, the papers do not hang together very well. All make some mention of wages, but this provides only a tenuous link. Knight's paper is a general exposition of the rationale of a competitive economy, with rather brief reference to wage-setting toward the end of the paper. Boulding restates the macro-economic theory of distribution first presented in his *Reconstruction of Economics,* the tenor of which is that events in the labor market may have relatively little to do with aggregate distributive shares. Wright's first paper (there are two in the volume) discusses the dilemma of progress versus security along lines reasonably familiar from his earlier writings. Samuelson reviews and criticizes different types of theorizing about wages which have been important over the past century or so. The merit of the book consists in the brilliance of some of the papers as discrete entities, rather than in any unified reconstruction of wage theory. An integrated treatment is not achieved, and doubtless could not have been achieved in this sort of symposium.

It was probably overambitious to title this volume *The Impact of the Union.* One may well ask, "*Which* impact?" Leaving aside all noneconomic effects, there are many economic consequences of collective bargaining which do not operate via the wage structure—effects on the size and composition of the labor force, allocation of jobs, labor mobility and turnover, worker effort and efficiency, production methods, plant location, marketing and competitive tactics. While the quantitative importance of these effects is difficult to judge, it would not be surprising if wage effects turned out to be a minor part of the total. Nor is it very useful to say that any cost effect of unionism can be assimilated for theoretical purposes to a wage change. This is to work at a level of generality which veils many of the most significant problems. While the contributors to the volume doubtless realize all this, the dominant emphasis on wages conveys an impression that other economic effects are regarded as less important.

Again, what significance can be attached to "*the* union"? This implies a homogeneity in union policies and tactics which does not exist. Even within the United States, national union policies show significant variation at a given time and change over the course of time. Several of the papers imply that everybody knows what a union is and what it does, that theoretical reasoning

can safely start from simple premises which are matters of common knowledge. This is certainly a dubious position, which may lead to waste of theoretical ingenuity in analyzing cases quite remote from reality.

Theorists might reply that labor economists have not yet provided usable generalizations about union behavior and that, in the absence of empirically grounded assumptions, they are forced to proceed as best they can on an intuitive basis. While there is something to this, some of the papers in this volume fail to draw even on the limited knowledge of union behavior which we do have. It would certainly have been a good idea to include a student of trade unionism in the conference. The categories "theorist" and "labor economist," while they do not coincide as closely as one might wish, are not so mutually exclusive as the list of contributors to this volume would suggest.

The traditional (and doubtless healthy) tendency of economists to view with alarm is evident throughout the volume, but something new has been added. Earlier economic critiques of trade unionism emphasized mainly its effects on relative wage rates and on resource allocation. The main fear expressed in this volume, however, is that the *general* level of money wage rates may rise too rapidly as a result of union activities. Cost-induced inflation may produce a chronic tendency toward rising prices accompanied by unemployment, or frequent declines in employment if the monetary authorities attempt to hold prices in check. The mechanisms involved are suggested in Haberler's skilful and lucid analysis.

Friedman suggests that our present fears on this score may be exaggerated, and that the effect of unionism both on wage structure and on the money wage level may be overstated in popular discussion. This is an interesting paper, the only one in the volume which makes frequent reference to empirical evidence. The reviewer is inclined to share Friedman's doubts about the importance of union wage effects in the postwar period. Looking back twenty years from now, it may turn out that present theories of chronic inflation are as lopsided as were our theories of perpetual depression in the late 'thirties. Even economists are too largely creatures of their times.

If the problem does exist, something should presumably be done about it. There is something like a consensus among the authors that not much reliance can be placed on monetary-fiscal restraints on inflation, because of the unwillingness of a democratic government to risk a serious recession. Beyond this, however, there is little in the way of positive prescription. Several contributors appear to hope that union bargaining power can be reduced by restricting unions to a one-company basis, by curbing certain types of union tactic, and so on. These proposals are not pressed very seriously, however, and one suspects that even their proponents doubt their workability. Clark, in a typically statesmanlike paper, explores the possibility of bringing about changes in union behavior, of subordinating short-run conceptions of the union's interest to longer-run definitions of self-interest The fact that none of the authors appears highly optimistic about this or any other approach simply reflects the general state of mind of economists on this matter.

This is certainly a book which deserves to be read by economists generally,

not simply by students of labor. It should have considerable usefulness for graduate students and for the more capable undergraduates. It is bound to provoke dissent, quite possibly indignant dissent, in some quarters. If this leads to more and better work on wage questions, however, the authors will not have labored in vain.

Population; Social Welfare and Living Standards

Grundriss der Bevölkerungswissenschaft (Demographie). By RODERICH V. UNGERN-STERNBERG and HERMANN SCHUBNELL. (Stuttgart: Piscator-Verlag. 1950. Pp. viii, 602. DM 42.—.)

This book by two experienced German demographers embodies an effort to present a systematic analysis of population questions. It commences with the study of the main features by which a population may be characterized and measured, *e.g.*, households, size of town or city, trade and social position, occupation, age and sex, health and educational attainments. With this groundwork laid, population is studied in its process of renewal through natural change arising out of births and deaths. The subject is covered by establishing some pivotal position which is traced in its various admixtures and correlations. Systematically canvassed in this fashion are available materials on the family and marriage, births and deaths. These materials are then recapitulated in summary of resultant population movements and problems of their measurement and forecasting. By restricting canvass and compressing treatment, rapid disposition is made of the three remaining major topics: migration and processes of spatial population movement, impact of war on population, and population policy and theory.

The work achieves an externally efficient mode of organization of its materials but at the cost of much repetition of subject matter and superficiality of treatment. Repetition is involved since the study of phenomena in their statistically emergent forms (thus birth rate, family size, child mortality, population growth) involves segregated treatment not of different aspects of a process but only of different statistical expressions of it. The analysis remains at the surface level for the most part. Thus in the treatment of population as an aggregate only the most superficial review of statistical findings about population is given. No effort is made to differentiate social systems according to the way in which population is handled. And since the authors regard all aggregative phenomena concerning population as suitable for inclusion within their discipline, the inner connection of these phenomena are lost while attention is concentrated on classification or registration of their outward features.

Even as a handbook the work is deficient. Though most of its bulk is taken up with presenting data on a world basis, both the scope and adequacy of the reporting are limited. Undue prominence is given to recent German developments; little systematic attention is given to population phenomena in non-

European societies; and little use is made—both on the analytic and informational side—of the immense wealth of pertinent monographs and literature outside Germany on the subject. Thus the chapter on internal population movement or mobility fails to take account of the American literature on ecological research and Sorokin's basic monograph on social mobility. Very little in French population literature is cited and of the American literature the authors show acquaintance chiefly with Thompson's text, *Population Problems.* As usual little attention is given to Malthus' positive analysis in the field of demography though the customary homage to his name is paid in the skimpy chapter on the history of population policy. Thus the chapter of the book dealing with the impact of war on population (confined, by the way, chiefly to the statistical registration of the effects of World War I on leading belligerent countries) could have taken as a point of departure Malthus' perceptive analysis directed to the failure of the Napoleonic wars to affect more prominently than it did French population growth (see Bk. II, Ch. 6, of Malthus' *Essay,* later editions).

Though the work is unsuitable as a handbook, it occasionally brings to light some interesting materials. Thus on many relatively obscure questions (such as marriage rates by calendar months, illegitimacy, twins, institutional births, etc.) information not otherwise readily available might be found in this work. American students will be particularly interested in the presentation of German census reports on family size of completed marriages published in Germany during the war and released in a form not readily available in most American libraries. These reports provide "cohort" information on family size in a detail matched by few countries (see pp. 266-77). Comparison of the French and German data on family size in the 'thirties brings to light that differences between countries as to average family size arise from different assortments of family types—the relative weight of the sterile couple, the short 2-3 children family and the long over-4 family—and not from any absolute differences in behavior or modal performance. It is highly likely that the whole modern reduction of the birth rate below reproductive levels reflects the growth in sterile marriages, a slight increase in the rôle of one and two-child families, and the marked diminution in the number of families rearing to adulthood four or more children. But instead of concentrating on this crucial outcome and drawing on more complex and remote levels of experience and causation to explain it, this work like so much of the recent literature in the field obscures fundamental issues by failing to give them the central importance they deserve. It is also worth noting that the discussion of German data on family size does not make a comparative analysis of recent British and American data on the same subject.

MANUEL GOTTLIEB

University of Kansas City

TITLES OF NEW BOOKS

Economic Theory; General Economics

BAUDIN, L. *Manuel d'économique politique.* Vol. 1. (Paris: Lib. Générale de Droit et de Jurisprudence. 1953. Pp. 624.)

This is the seventh edition of this text in principles of economics. The first volume, after a short history of economic thought and after providing definitions of economics, needs, goods, utility, etc., is devoted to the subjects of population, the price mechanism, production, money and credit.

BOULDING, K. E. *The organizational revolution—a study in the ethics of economic organization.* With commentary by Reinhold Niebuhr. Ser. on Ethics and Econ. Life by a study committee of the Federal Council of Churches. (New York: Harper & Bros. 1953. Pp. xxxiv, 286. $3.50.)

BRESCIANI-TURRONI, C. *Corso di economia politica.* Vol. 1, *Teoria generale dei fatti economici.* Rev. ed. (Milan: D. A. Giuffrè. 1953. Pp. 434.)

The second edition of a book originally published in 1949. Additional examples of the quantitative analysis of economic phenomena are provided; and a summary account of the author's investigations on the subject of Pareto's Law, first published some decades ago, is also included.

CHARNES, A., COOPER, W. W., and HENDERSON, A. *An introduction to linear programming.* (New York: John Wiley & Sons. 1953. Pp. ix, 74. $2.50.)

Part 1 is an economic introduction to linear programming and contains sections designed to indicate the nature of linear programming for the nonspecialist, as well as sections for the person interested in concrete applications of the technique. The final sections of this part deal with more advanced materials. Part 2 is devoted to the mathematical theory of linear programming, but is "designed so that a minimum of beginning background mathematics is required."

DATTA, B. *The economics of industrialisation—a study of the basic problems of an underdeveloped economy.* (Calcutta: The World Press. Ltd. 1952. Pp. vi, 291. Rs. 12.8; 21 *s.*)

"The present study examines the impact of the employment and output approach on the economic policy of underdeveloped countries and analyses the cyclical, seasonal and structural problems of underemployment vis-à-vis the prospects and difficulties of industrialisation. Special emphasis has been put on the significance of 'disguised unemployment' as relevant to backward economies, the relative importance of the determinants of employment and income, the relation between the occupation-pattern and resource-utilisation, the problem of the 'surplus agricultural population' and the problem of measuring this surplus under changing resource-utilisation and changing terms of trade."

DEHEM, R. *L'efficacité sociale du système économique.* (Louvain: Institut de Recherches Econ. et Soc. 1952. Pp. 184. $3.)

A review of recent and contemporary welfare economics with primary emphasis upon the theory concerned with optimum use of resources. Because the author finds a contemporary dichotomy between two theories of social welfare—that concerned with optimum use of resources, and the theory of employment—he also includes a treatment of the latter and considers the possibility of an integration of these two aspects of welfare economics in the broader sense.

EUCHEN, W. *Grundsatze der wirtschaftspolitik.* (Bern: Francke. Tubingen: J. C. B. Mohr. 1952. Pp. lx, 396.)

EUGSTER, C. *Thorsten Bunde Veblen, 1857-1929. Darstellung und Deutung amerikanischen institutionellen Denkens aus seinem Werk heraus.* (Zurich: Europa Verlag. 1952. Pp. 116. 116 *s.*, Kart. fr. 6.75.)

FOSSATI, E. *Frammenti di teoria dinamica.* (Trieste: Università di Trieste. 1952. Pp. x, 135.)

FOURASTIÉ, J. *La productivité.* No. 557 of the collection Que sais-je? (Paris: Presses Univ. de France. 1952. Pp. 118. 150 fr.)

The approach of this little book is similar to that of the author's major work cited below.

———. *Le grand espoir du XXe siècle—progrès technique, progrès économique, progrès social.* 3d ed. (Paris: Presses Univ. de France. 1952. Pp. xxviii, 245. 320 fr.)

The object of the author is to show the economic consequences of technical progress. The approach is a very broad one. There are chapters on migration, the evolution of capitalism, unemployment (technological and cyclical), international trade and world equilibrium, and the level of living.

GEMMELL, J. and BALSLEY, H. L. *Principles of economics.* (New York: D. C. Heath. 1953. Pp. xiii, 589. $4.75.)

GRAMPP, W. D. and WEILER, E. T., editors. *Economic policy—readings in political economy.* (Homewood, Ill.: Richard D. Irwin. 1953. Pp. xiii, 393. $3.75.)

A collection of readings on four main areas of economic policy: stability, the control of monopoly power, the distribution of income, and international economic relations. "The book is meant for courses in principles of economics, and it also can be used in courses in government and business, economic problems, and economic planning." The selection of materials appears excellent.

HARROD, R. F. *Economic essays.* (New York: Harcourt, Brace & Co. 1953. Pp. xiii, 301. $4.50.)

HENDERSON, J. S. *Production and consumption—a mathematical reformulation.* Univ. of Alabama stud. no. 7. (University, Ala.: Univ. of Alabama Press. 1952. Pp. 83. $2.)

HIGGS, H. *The Physiocrats—six lectures on the French* Économistes *of the 18th Century.* Reprint of the English ed. of 1897. (New York: The Langland Press. 1952. Pp. x, 158. $3.25.)

HUTCHISON, T. W. *A review of economic doctrines—1870-1929.* (Oxford, Eng.: Clarendon Press. 1953. Pp. xiv, 456. $6.)

LAGLER, E. and MESSNER, J., editors. *Wirtschaftliche Entwicklung und soziale Ordnung.* (Vienna: Verlag Herold. 1952. Pp. 456. $6.)

MARCHAL, A. *La pensée économique en France depuis 1945.* (Paris: Presses Univ. de France. 1953. Pp. vii, 240. 700 fr.)

MACHLUP, F. *The economics of sellers' competition: model analysis of sellers' conduct.* (Baltimore: Johns Hopkins Press. 1952. Pp. xx, 582. $6.50.)

PIGOU, A. C. *Essays in economics.* (New York: St. Martin's Press. 1952. Pp. vii, 241. $3.)

A collection of economic papers, mostly nontechnical in character, that have (with three exceptions) appeared elsewhere since 1939. The three new papers are: "The 'Value' of Different Kinds of Transfer Payment," a short review of *Poverty and the Welfare State,* by Rowntree and Labers; "The Inflationary Gap," written in 1951; and "The Gold and Dollar Reserve," written in the spring of 1952. The volume also includes "Wage Statistics and Wage Policy," the University of London Stamp Memorial lecture, 1949 (published earlier by the Oxford University Press); "One Way of Looking at Economics," printed in *Economica,* January 1951; "Employment Policy," a review of *Full Employment in a Free Society,* by Sir William Beveridge; and numerous shorter essays.

POOL, A. G. *Economists and social policy.* (Leicester: Univ. College, Leicester. 1952. Pp. iii, 20. 1 *s.*)

RÖPER, B. *Die Konkurrenz und ihre Fehlentwicklungen—Untersuchungen über Störungen der Marktwirtschaft.* (Berlin: Duncker & Humblot. 1952. Pp. 243. DM 14,60.)

STARK, W. *Jeremy Bentham's economic writings.* Vol. 1. (New York: Burt Franklin. 1952. Pp. 412.)

TINBERGEN, J. *On the theory of economic policy.* Contributions to Economic Analysis, I., edited by J. Tinbergen, P. J. Verdoorn and H. J. Witteveen. (Amsterdam: North-Holland Pub. Co. 1952. Pp. 80. $1.80.)

WARD, A. D., editor. *Goals of economic life.* Ser. on Ethics and Econ. Life by a study committee of the Federal Council of Churches. (New York: Harper. 1952. Pp. x, 470. $4.)

WILLIAMS, J. H. *Economic stability in a changing world: essays in economic theory and policy.* (New York: Oxford Univ. Press. 1953. Pp. 234. $5.)

John R. Commons, teacher, economist and administrator. Addresses delivered on Oct. 10, 1950, in commemoration of his achievements. (Madison: State Historical Soc. of Wisconsin. 1952. Pp. vii, 23.)

Problèmes économiques contemporains. Colloquia de la chaire Francqui 1951-52. (Liège: Faculté de Droit de l'Université de Liège. 1953. Pp. viii, 150.)

Studi Keynesiani. Prepared by the Instituto di Economia e Finanza della Facoltà Giuridica di Roma. (Milan: A Giuffrè. 1953. Pp. xi, 385. L. 1500.)

Economic History; National Economies; Economic Development

ALLBAUGH, L. G. *Crete, a case study of an underdeveloped area.* Report of a study carried out by the Rockefeller Foundation. (Princeton: Princeton Univ. Press. 1953. Pp. xx, 572. $7.50.)

BOG, I. *Die Bäuerliche Wirtschaft im Zeitalter des dreissigjährigen Krieges.* (Coburg: Veste Verlag. 1952. Pp. xiii, 180.)

CALL, T. C. *The Mexican venture—from political to industrial revolution in Mexico.* (New York: Oxford Univ. Press. 1953. Pp. xii, 273. $4.50.)

The book is concerned with social, economic, and political aspects of recent developments in Mexico. "It is an effort to appraise, in the light of recorded facts and personal observation, all major phases of modern Mexican life, to view what the Revolution has accomplished toward forging a nation, and to consider what the future may hold for the people."

CLOUGH, S. B. *The American way—the economic basis of our civilization.* (New York: Thomas Y. Crowell. 1953. Pp. viii, 246. $4.)

COOKE, H. V. *Challenge and response in the Middle East—the quest for prosperity, 1919-1951.* (New York: Harper. 1952. Pp. 366.)

CZARNOMSKI, F. B. *Can Russia survive? An examination of the facts and figures of Soviet reality.* (New York: Philosophical Library. 1953. Pp. 128. $2.75.)

EATON, J. *Economics of peace and war—an analysis of Britain's economic problems.* (New York: Internat. Publishers. 1953. Pp. 112. $1.50.)

A very pessimistic view of the future of the British economy is presented. "As part of the capitalist world Britain is dragged down with the capitalist world as a whole. But on top of this British imperialism faces its own crisis." The British Labour Party's program was a retreat from socialism. The Marshall Plan was designed "to coordinate ('integrate') Europe in such a manner as would, the Americans hoped, bring it under the economic and political control of the U.S.A. and prepare the way for the aggressive military plans that took shape in N.A.T.O." And so on.

FRIEDLAENDER, H. E. and OSER, J. *Economic history of modern Europe.* (New York: Prentice-Hall. 1953. Pp. xxiv, 611. $6.)

GAYER, A. D., ROSTOW, W. W., SCHWARTZ, A. J. *The growth and fluctuation of the British economy 1780-1850.* 2 vols. (New York: Oxford Univ. Press. 1953. Pp. xix, 528; xii, 1028. Vols. I & II, $17.)

GUTIERREZ, G. *El desarrollo économico de Cuba.* Estud. e Investigaciones Econ. ser. no. 12. (Havana: Junta Nacional de Economia. 1952. Pp. xxi, 257.)

HUGHES, E. *North country life in the eighteenth century: The north east 1700-1750.* (New York: Oxford Univ. Press. 1952. Pp. xxi, 435. $6.)

Based upon a collection of 18th century manuscripts discovered in 1940—the letters, account books, and other papers of the lords of the manors of Gateshead and Whickham, "once the richest coal-bearing manors in this country" (From the preface).

JENNINGS, W. W. *Twenty giants of American business: biographical sketches in economic history.* (New York: Exposition Press. 1953. Pp. 480. $5.)

JONES, N. S. C. *The pattern of a dependent economy: a study of the national income of British Honduras.* (New York: Cambridge Univ. Press. 1953. Pp. xv, 162. $4.)

National income tables for British Honduras for 1946 have been prepared, in spite of the difficulty in finding adequate data. The author has had two aims: "first, to show that a reasonably accurate national income study, in broad outline, can be made without overloading it with detail or spending an inordinate time in detailed research; and, secondly, to indicate some of the problems peculiar to a dependent economy by an examination in some detail of one."

KUCZYNSKI, J. *Studien zur Geschichte des deutschen Imperialismus.* I, *Monopole und Unternehmernerbände.* (Berlin: Dietz. 1952. Pp. v, 398.)

LANE, F. C., ed., assisted by RIERMERSMA, J. C. *Enterprise and secular change—readings in economic history.* (Homewood, Ill.: Richard D. Irwin, for the Am. Econ. Assoc. and the Econ. Hist. Assoc. 1953. Pp. xi, 556.)

MAYER, A. C. *Land and society in Malabar.* Issued under auspices of Internat. Secretariat Inst. of Pacific Relations. (New York: Oxford Univ. Press. 1952. Pp. vii, 158. $3.)

"This book is an analysis of the social system of one part of India in relation to its most important base, the system of agriculture."

MULHAUPT, L. *Strukturwandlungen und nachkriegsprobleme dere wirtschaft Schwedens.* (Kiel: Institut fur Weltwirtschaft, Universität Kiel. 1952. Pp. iii, 187.)

MÜLLER-OHLSEN, L. *Strukturwandlungen und Nachkriegsprobleme der Wirtschaft Frankreichs.* Kieler stud. 22. (Kiel: Institut fur Weltwirtschaft, Universität Kiel. 1952. Pp. vii, 205. Dm. 16.-.)

SEERS, D. and ROSS, C. R. *Report on financial and physical problems of development in the Gold Coast.* (Accra, Gold Coast: Govt. Printing Office. 1952. Pp. iii, 65. 5 *s.*)

SUMMERS, F. P. *William L. Wilson and tariff reform.* (New Brunswick: Rutgers Univ. Press. 1953. Pp. xi, 288. $5.)

The biography of a political leader of the Cleveland era who championed a low tariff.

TWITCHELL, K. S. *Saudi Arabia—with an account of the development of its natural resources.* 2nd ed. (Princeton: Princeton Univ. Press. 1953. Pp. xxi, 231. $5.)

WORSWICK, G. D. N. and ADY, P. H., editors. *The British economy 1945-1950.* (Oxford: Clarendon Press. 1952. Pp. viii, 621. $9.)

ZARCHIN, M. M. *Economic structure of Europe.* (San Francisco: Author, City College of San Francisco. 1952. Pp. 379, mimeo.)

This is an elementary text in European economic history which offers as its special feature the inclusion of chapters on the development of the economic structure of the Soviet Union.

The economic development of Ceylon. Report of a mission of the Internat. Bank for Reconstruction and Development at the request of the government of Ceylon. (Baltimore: Johns Hopkins Press. 1953. Pp. xxxii, 829. $7.50.)

The economic development of Jamaica. Report by a mission of the Internat. Bank for Reconstruction and Development. (Baltimore: Johns Hopkins Press. 1952. Pp. xviii, 288. $5.)

Methods and problems of flood control in Asia and the Far East. Flood Control ser. no. 2. 1951. UN pub. II. F. 5. (New York: Columbia Univ. Press. 1951. Pp. 45. $1.15.)

Puerto Rico—a study in democratic development. (Philadelphia: Am. Acad. of Pol. and Soc. Sci. The Annals, Jan., 1953. Pp. 166.)

Soviet economic development. Bull. 7, ser. 2: *Finance,* by R. W. Davies; *Note on the Productivity of labour in industry,* by G. R. Barker; and *Note on compulsory labour in the U.S.S.R.,* by A. Baykov. (New York: Frederick A. Praeger, for the Dept. of Econ. and Institutions of the U.S.S.R., Univ. of Birmingham, England. 1952. Pp. 46.)

Statistics and Econometrics

CLARK, C. E. *An introduction to statistics.* (New York: John Wiley & Sons. London: Chapman & Hall. 1953. Pp. x, 266. $4.25.)

HOFSTEN, E. V. *Price indexes and quality changes.* (Stockholm: Bokforlaget Forum Ab. London: Allen & Unwin. 1952. Pp. v, 136. 26 *s.*)

SHEPHARD, R. W. *Cost and production functions.* (Princeton: Princeton Univ. Press. 1953. Pp. vii, 104. $2.)

Starting from the work of G. C. Evans, the author has formulated, in mathematical terms, an integrated theory of cost and production functions.

WOLD, H., in association with JURÉEN, L. *Demand analysis: a study in econometrics.* (New York: John Wiley. 1953. Pp. xvi, 358. $7.)

The consumer price index; a short description of the index as revised, 1953. (Washington: Bur. of Labor Statistics. 1953. Pp. 10.)

Economic theory and measurement—a twenty year research report, 1932-1952. (Chicago: Cowles Commission for Research in Economics, Univ. of Chicago. 1952. Pp. 180.)

Progress report of the Inter-American Statistical Institute (IASI) July 1, 1951-June 30, 1952. Suppl. 1, Estadistica, Dec. 1952. (Washington: Inter-American Statistical Inst. 1952. Pp. 47.)

Economic Systems; Planning and Reform; Cooperation

ANGELOPOULOS, A. *Planisme et progrès social.* (Paris: Lib. Générale de Droit et de Jurisprudence. 1953. Pp. 403. Fr. 1200.)

The author undertakes to explain "the new economic and social policy of the 'Welfare State'," which, he believes, must be based upon "democratic planning." The objectives of full employment and methods of maintaining it, the economic development of backward countries, measures for raising the level of living and for achieving social security, fiscal policy and redistribution of income, monetary policy and the attack upon inflation are discussed from this point of view.

BETTELHEIM, C. *Problèmes théoriques et pratiques de la planification.* (Paris: Presses Univ. de France. 1951. Pp. 395. Fr. 1200.)

COLE, G. D. H. *Socialist thought . . . the forerunners. 1789-1850.* Hist. of Socialist Thought, vol. I. (New York: St. Martin's Press. 1953. Pp. xi, 346. $5.)

This book is designed to be the first of a series of volumes that will together constitute a general history of socialist thought. In the present volume the story is carried through the European revolutions of 1848 and the Communist Manifesto. However, "no full exposition of Marxism is attempted in this volume, . . ."

HAYNES, W. W. *Nationalization in practice: the British coal industry.* (Boston: Div. of Research, Harvard Business School. 1953. Pp. xviii, 413. $4.)

KEILHAU, W. *Principles of private and public planning: a study in economic sociology.* (New York: Burt Franklin. 1952. Pp. 272.)

PENROSE, E. F. *Economic planning for the peace.* (Princeton: Princeton Univ. Press. 1953. Pp. xiv, 384. $7.50.)

RUNES, D. D. *The soviet impact on society—a recollection.* (New York: Philosophical Lib. 1953. Pp. xiii, 202. $3.75.)

As Harry Elmer Barnes points out in his introduction to the volume, the author "presents a sharp and consistent criticism of Marxist doctrine and Soviet practice, . . ."

National Income and Social Accounting

CHAPMAN, A. L., asst. by KNIGHT, R. *Wages and salaries in the United Kingdom, 1920-1938.* Stud. in national income and expenditure of the United Kingdom, no. 5. (New York: Cambridge Univ. Press. 1953. Pp. xiv, 253. $9.50.)

DOWNING, R. I. *National income and social accounts: An Australian Study.* (Melbourne: Melbourne Univ. Press. 1951. Pp. 58.)

KUZNETS, S. *Economic change: selected essays in business cycles, national income and economic growth.* (New York: W. W. Norton. 1953. Pp. viii, 333. $4.50.)

———. *Shares of upper income groups in income and savings.* Nat. Bur. of Econ. Research pub. no. 55. (New York: Nat. Bur. of Econ. Research. 1953. Pp. xli, 725. $9.)

KUZNETS and GOLDSMITH, R. *Income and wealth of the United States: trends and structure.* Internat. Assoc. for Res. in Income and Wealth, Income and Wealth ser. II. (Cambridge: Bowes and Bowes. 1952. Pp. vii, 328. 35 s.)

Measurement of productivity: methods used by the Bureau of Labor Statistics in the U.S.A. A report by a group of European experts. Technical Assistance Missions nos. 7-10-11. (Paris: Organisation for European Economic Co-operation. 1952. Pp. 104. $1.25.)

Nasjonalregnskap (national accounts) 1930-1939 and 1946-1951. (Oslo: Central Bur. of Stat. of Norway. 1952. Pp. 335.)

National income and expenditure, 1946-1951. G.B. Central Statistical Office pub. (London: H. M. Stat. Office. 1952. Pp. 91.)

Business Fluctuations; Prices

COLEAN, M. L. and NEWCOMB, R. *Stabilizing construction: the record and potential.* CED research stud. (New York: McGraw-Hill. 1952. Pp. 340.)

DROEGE, H. *Der Mensch als wirtschaftliches "Datum": Ein Beitrag zur Konjunkturforschung.* (Berlin: Duncker & Humblot. 1952. Pp. 72.)

JÖHR, W. A. *Die Konjunkturschwankungen—Theoretische grundlagen der Wirtschaftspolitik.* Vol. II. (Tübingen: J. C. B. Mohr (Paul Siebeck). 1952. Pp. xvi, 676, Br. fr. 37.45. Lw. fr. 41.20.)

The economic report of the President transmitted to the Congress Jan. 1953. Together with a report to the President, the *Annual Economic Review,* by the Council of Economic Advisers. (Washington: Supt. Docs. 1953. Pp. v, 218. 50¢.)

Markets after the defense expansion. A report of the Dept. of Commerce. (Washington: Supt. Docs. 1952. Pp. v, 90. 55¢.)

The sustaining economic forces ahead. Materials prepared for the Joint Committee on the Economic Report by the committee staff. 82nd Cong. 2nd sess. (Washington: Supt. Docs. 1952. Pp. viii, 70.)

Money and Banking; Short-Term Credit; Consumer Finance

DUNKMAN, W. E. *A study of savings and savings facilities in New York State, 1941 and 1950.* (New York: New York State Bankers Assoc. 1952. Pp. x, 147. $5.)

FLAMANT, M. *Théorie de l'inflation et politiques anti-inflationnistes. Essai d'application de concepts Keynésiens.* (Paris: Lib. Dalloz. 1952. Pp. xii, 231.)

In the first part the author presents a theoretical analysis of inflation with Keynesian theory as a point of departure. In the second part various policies for combatting inflation are considered, and again Keynesian ideas come in for attention.

FOSTER, M. B., RODGERS, R., BOGEN, J. I., and NADLER, M. *Money and banking.* 4th ed. (New York: Prentice-Hall. 1953. Pp. xiv, 633. $5.95.)

GABILLARD, J. *La fin de l'inflation.* Observation Economique collection publiée sous la direction de André Platier. (Paris: Societé d'Edition d'Enseignement Superieur. 1952. Pp. xxxvi, 359.)

LUTOLF, F. *Die Theorie der monetären Kreislaufsphären.* (Bern: A. Francke. 1952. Pp. 137. Sw. fr. 10.50.)

SAYERS, R. S., editor. *Banking in the British Commonwealth.* (New York: Oxford Univ. Press. 1952. Pp. viii, 486. $7.)

A collection of essays by different authors on the banking systems of British Commonwealth countries. The latter include Australia, Canada, India, Pakistan, Ireland, New Zealand, South Africa, Ceylon. There are also chapters on "The Colonial Empire," and "The Sterling Area."

SMITH, W. B. *Economic aspects of the Second Bank of the United States.* (Cambridge: Harvard Univ. Press. 1953. Pp. xii, 314. $5.)

The Federal Home Loan Bank System, 1932-1952. (Washington: Federal Home Loan Bank Board. 1952. Pp. 73.

Mortgage interest rate problem. Hearing before the Senate Committee on Banking and Currency, 83d Cong., 1st sess. (Washington: Supt. Docs. 1953. Pp. 93.)

Rapport sur les opérations de l'année 1952 de Banque Nationale de Belgique presenté par le gouverneur au nom du Conseil de Régence. (Bruxelles: Banque Nat. de Belgique. 1953. Pp. 140.)

Saudi Arabian Monetary Agency. (Jidda, Saudi Arabia: Ministry of Finance. 1952. Pp. 25.)
Royal decrees, charter and by-laws of the Agency, with a report on Establishment of the Agency by Arthur N. Young, financial advisor.

Business Finance; Investments and Security Markets; Insurance

BRADLEY, J. F. *Fundamentals of corporation finance.* (New York: Rinehart. 1953. Pp. xix, 583. $6.)

GRODINSKY, J. *Investments.* (New York: Ronald Press. 1953. Pp. xii, 567. $6.)

HOWARD, B. B. and UPTON, M. *Introduction to business finance.* (New York: McGraw-Hill. 1953. Pp. x, 565. $6.)

KNOWLTON, P. A. *Studies in profit sharing.* (Long Island City, N.Y.: Profit-Sharing Research Foundation. 1953. Pp. 32. $1.)

MALISSEN, M. *L'autofinancement des sociétés en France et aux États-Unis.* (Paris: Lib. Dalloz. 1953. Pp. xiv, 246.)
Internal corporate financing as it has developed in France (since 1921) and the United States (since 1909), and an interpretation of its economic consequences.

The cost and availability of credit and capital to small business. Staff report to the Board of Governors of the Federal Reserve System submitted to the Subcommittee on Monopoly of the Senate Select Committee on Small Business. (Washington: Supt. Docs. 1952. Pp. 37.)

Study of Securities and Exchange Commission—hearings before a subcommittee of the Committee on Interstate and Foreign Commerce, 82nd Cong., 2nd sess. on powers, duties and functions of Securities and Exchange Commission. (Washington: Supt. Docs. 1952.)

Study of the Securities and Exchange Commission. 82nd Cong. Final report of the Securities and Exchange Commission Subcommittee to the Committee on Interstate and Foreign Commerce. (Washington: Supt. Docs. 1952. Pp. 152.)

The work of the Securities and Exchange Commission. (Washington: Supt. Docs. 1952. Pp. 32.)

Public Finance

ABBOTT, C. C. *The federal debt—structure and impact.* With policy recommendations of the Committee on the Federal Debt. (New York: Twentieth Century Fund. 1953. Pp. xvii, 278. $4.)

CHATTERS, C. H. and HAMILTON, R. N. *Federal grants and controls affecting municipalities.* (Chicago: Am. Municipal Assoc. 1952.)

KANNINS, R. M. *The tax system of Hawaii.* (Honolulu: Univ. of Hawaii Press. 1952. Pp. xii, 194. $2.50.)

MARTIN, J.-P. *Les finances de guerre du Canada.* (Paris: Lib. Armand Colin. 1951. Pp. vi, 212. 600 fr.)

MORSELLI, E., editor. *Archivio finanziario.* Vol. III. (Padova: Cedam. 1953. Pp. x, 551. L. 3600.)

MYERS, W. S., JOHNSON, J. L., and MARTIN, J. W. *Kentucky income payments by counties: 1939, 1947, 1950 and 1951.* Bull. no. 26 of Bur. of Bus. Research, College of Commerce, Univ. of Kentucky. (Lexington: Univ. of Kentucky, Bur. of Bus. Research. 1953. Pp. iv, 37.)

RHYS-WILLIAMS, Lady. *Taxation and incentive.* (New York: Oxford Univ. Press. 1953. Pp. 188. $3.50.

SINGH, B. *Federal finance and underdeveloped economy.* (Bombay: Hind Kitabs. 1952. Pp. v, 176. Rs. 10/-.)

The author is concerned with "the restoration of the efficiency test for judging the soundness of economic policy and measures" for enlarging the national dividend in underdeveloped economies. "Functional finance and contracyclical compensatory fiscal policies and programmes are not wholly effective in bringing about optimum resource allocation . . . I have formulated a concept of optimum budget, at which national net product in relation to aggregate resources is at its maximum."

SMEETS, M. J. H. *Bevorderen hoge belastingen de bedrijvigheid?* A speech at the Tilburg R. C. School of Economics, Dec. 12, 1952. (Amsterdam: L. J. Veen's Uitgeversmij N. V. 1952. Pp. 31. *f.* 1.50.)

Additional report of the Joint Committee on Reduction of Nonessential Federal Expenditures, 83d Cong., 1st sess. Senate committee prints nos. 1 and 2. (Washington: Supt. Docs. 1953. Pp. 53; 44.)

The budget of the United States government for the fiscal year ending June 30, 1954. (Washington: Supt. Docs. 1953.)

Compendium of city government finances in 1951. Bur. of the Census pub. (Washington: Supt. Docs. 1952. Pp. 126.)

Coordination of federal, state, and local taxes. Report to the House Committee on Ways and Means, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1953.)

The federal budget in brief, fiscal year 1954. (Washington: Supt. Docs. 1953. Pp. 44.)

Federal supply management (implementation of military supply regulations). Hearings held by a subcommittee of the House Committee on Expenditures in the Executive Departments, Dec. 3, 4, 5, 1952, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1953. Pp. 375.)

Federal tax changes and estimated revenue losses under present law. (Washington: Joint Committee on the Economic Report. 1952. Pp. 14.)

A library of public finance and economics. (Montreal: McGill Univ. Book Store. 1953. Pp. 383, mimeo.)

A catalogue of the collection of Jan M. Novotny removed to Canada from Prague with the help of McGill University after the 1948 Communist coup in Prague. About 5000 volumes are included.

U. S. Bureau of the Budget—functions and organization. (Washington: Bur. of the Budget. 1952. Pp. 5, mimeo.)

Your federal income tax for individuals. (Washington: Bur. of Internal Revenue. 1952. Pp. 148.)

International Economics

ALEXANDROWICZ, C. H. *International economic organisations.* Pub. under auspices of the London Inst. of World Affairs. (New York: Frederick A. Praeger. 1953. Pp. xii, 263. $6.)

BONN, M. J. *Whither Europe. Union or partnership.* (London: Longmans. 1952. Pp. v, 256. 18 *s.*)

CURTISS, W. M. *The tariff idea.* (Irvington-on-Hudson: Foundation for Economic Education. 1953. Pp. 80. 50¢.)

HAUSSMANN, F. *Der Schuman-Plan im Europäischen Zwielicht.* (Berlin: C. H. Beck. 1952. Pp. xii, 266. DM 16.–)

KNORR, K. *Strengthening the free world economy.* A report of a conference held at Princeton Univ., Dec. 16-17, 1952. (Princeton: Center of International Stud., Princeton Univ. 1953. Pp. 45.)

KRISHNA, V. S. *International economic co-operation: (Sir William Meyer lectures for 1949-50.)* (Madras, India: Univ. of Madras. 1952. Pp. 146.)

The subjects of the six lectures are: The 19th Century World Economic Order; Disintegration and Beginning of Mutual Aid; Extraordinary Aids; Chronic Disequilibrium and World Economic Development; Technical Assistance and Provision of Long-Term Capital; Equitable Exchange Rates and Non-discrimination.

MAFFRY, A. *Program for increasing private investment in foreign countries.* Report prepared for Technical Cooperation Admin. (Dept. of State), Dept. of Commerce and Mutual Security Agency. (Washington: Dept. of State. 1952. Pp. 40.)

MARX, D. JR. *International shipping cartels: a study of industrial self-regulation by shipping conferences.* (Princeton: Princeton Univ. Press. 1953. Pp. xii, 323. $6.)

MEADE, J. E. *Problems of economic union.* (Chicago: Univ. of Chicago Press. 1953. Pp. ix, 102. $1.75.)

This book is based upon lectures delivered in 1952 at the University of Chicago under the auspices of the Charles R. Walgreen Foundation for the Study of American Institutions.

SCHUMAN, R. *Le Plan.* (Strasbourg: Pabli-Europe. 1952. Pp. iii, 127. 1.20 Mk.)

STEINER, G. A. *Government's role in economic life.* (New York: McGraw-Hill. 1953. Pp. xi, 440. $6.)

The alien property custodian: a legislative chronological history and bibliography of the Trading with the Enemy act and the operations of the Office of Alien Property Custodian, 1917-1952. Prepared by Legis. Ref. Service, Library of Congress. (Washington: Supt. Docs. 1953. Pp. 50.)

Bills relating to War Claims act of 1948 and Trading with the Enemy act. Hearings before the House Committee on Interstate and Foreign Commerce, 82nd Cong., 1st and 2nd sess. (Washington: Supt. Docs. 1952. Pp. 318.

Effective competition. Report of the Business Advisory Council of the Dept. of Commerce with a letter of comment from the Secretary of Commerce. (Washington: Supt. Docs. 1952. Pp. 21.)

Elements of model charter for government corporations. Bur. of Budget staff memo. (Washington: Bur. of Budget, Office of Management and Organization. 1952. Pp. 40.)

The job ahead for defense mobilization. Eighth quarterly report to the President by the Director of Defense Mobilization, Jan. 1, 1953. (Washington: Supt. Docs. 1952. Pp. iv, 51. 30¢.)

Problems of economic defense—Mutual Defense Assistance Control Act of 1951 (the Battle Act)—Second Report to Congress, Jan. 1953. (Washington: Supt. Docs. 1953. Pp. iii, 89. 30¢.)

Production capacity: a military reserve. Report of the Advisory Committee on Production Equipment to the Director of Defense Mobilization. (Washington: Supt. Docs. 1953. Pp. 31.)

Review of small business. Final report of the House Select Committee on Small Business, 82nd Cong. (Washington: Supt. Docs. 1952. Pp. 310.)

Small business in a mobilization economy: fifth quarterly report of the Small Defense Plants Administration. (Washington: Small Defense Plants Admin. 1953. Pp. 64.)

Public Utilities; Transportation; Communications

LEWIS, E. H. *Minnesota's interstate trade.* (Minneapolis: Univ. of Minn. Press. 1953. Pp. vii, 47. $1.50.)

STOCKTON, J. R., HENSHAW, R. C. JR., GRAVES, R. W. *Economics of natural gas in Texas.* Bur. of Bus. Research monog. no. 15. (Austin: Univ. of Texas, Bur. of Bus. Research. 1952. Pp. xvi, 316. $5.)

Utilization of natural gas and natural-gas liquids, production, reserves, transportation, taxation of the Texas industry, public control, problems of conservation, and the competitive situation with respect to other fuels are the topics considered.

American merchant marine and the federal tax policy. A U.S. Maritime Administration report to the President submitted by the Secretary of Commerce. (Washington: Dept. of Commerce. 1952. Pp. 114.)

The role of competition in commercial air transportation. Report of the Civil Aeronautics Board submitted to the Subcommittee on Monopoly of the Senate Select Committee on Small Business, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 54.)

A study of future power transmission for the west. (Washington: Bur. of Reclamation. 1952. Pp. 30.)

Industry Studies

COLEAN, M. L. and NEWCOMB, R. *Stabilizing construction: the record and potential.* Committee for Economic Development research stud. (New York: McGraw-Hill. 1952. Pp. xvii, 340. $6.)

GLASER, E. *The interindustry economics research program of the federal government.* (Washington: Conf. on Research in Income and Wealth. 1952. Pp. 19.)

PASSER, H. C. *The electrical manufacturers—1875-1900.* (Cambridge: Harvard Univ. Press. 1953. Pp. xvii, 412. $6.)

One of the studies in entrepreneurial history prepared in cooperation with the Research Center in Entrepreneurial History, Harvard University. The book is concerned with: (1) Arc Lighting; (2) Incandescent Lighting; (3) Electric Power. In each case, attention is paid to the technological developments, the rise of leading firms, interfirm relations, entrepreneurship, and the dynamics of the industry.

Land Economics; Agricultural Economics; Economic Geography

BINDER, A. *Internationale Regulierungen auf dem Weltweizenmarkt.* (Kiel: Institut für Weltwirtschaft, Universität Kiel. 1952. Pp. vi, 93. DM 8,-.)

BLACK, J. D. *Introduction to economics for agriculture.* (New York: Macmillan. 1953. Pp. xv, 727. $6.)

DAVIDSON, R. D. *Federal and state rural lands, 1950, with special reference to grazing.* Dept. Agric. circ. no. 909. (Washington: Supt. Docs. 1952. Pp. 100.)

HALCROW, H. G. *Agricultural policy of the United States.* (New York: Prentice-Hall. 1953. Pp. xiii, 458. $5.50.)

LASSEN, L., LULL, H. W., and FRANK, B. *Some plant-soil-water relations in watershed management.* Dept. Agric. circ. no. 910. (Washington: Supt. Docs. 1952. Pp. 64.)

LEUBUSCHER, C. *The processing of colonial raw materials.* (London: H. M. Stat. Office. 1951. Pp. 11, 186. 10 *s.*)

NELSON, L. *Migratory workers: the mobile tenth of American agriculture.* Nat. Planning Assoc. pamph. no. 82. (Washington: National Planning Assoc., Feb. 1953. Pp. x, 33. 50¢.)

ORLANS, H. *Utopia Ltd.—the story of the English New Town of Stevenage.* (New Haven: Yale Univ. Press. 1953. Pp. xv, 313. $4.50.)

"In November 1946, the British Government founded the New Town of Stevenage, thirty miles north of London, as part of a long-term programme to move over a million people from the metropolis. This book tells the story of this New Town. . . . The book is, therefore, an historical and sociological study of a pioneering Government venture and of its impact upon a small town. It represents the results of interviewing, observation, and documentary research conducted over an eighteen-month period from October 1948." (From the Foreword.)

PARKS, W. R. *Soil conservation districts in action.* (Ames: Iowa State College Press. 1952. Pp. 242.

PRITCHARD, N. T. *Fall premium milk pricing plans.* Dept. Agric. Farm Credit Admin. circ. C-147. (Washington: Supt. Docs. 1952. Pp. 39.)

SCHULTZ, T. W. *Economic organization of agriculture.* (New York: McGraw-Hill. 1953. Pp. xx, 374. $4.)

SHIMKIN, D. B. *Minerals—a key to soviet power.* A Russian Research Center study prepared under a grant from the Carnegie Corp. of New York. (Cambridge: Harvard Univ. Press. London: Oxford Univ. Press. 1953. Pp. viii, 452. $8.)

Successive chapters examine the minerals resources of the Soviet Union: the use made of them, foreign trade, reserves, and potentials. The major classes of minerals are considered, with due regard for the precautions necessary in utilizing the available statistical materials: ferrous and nonferrous metals; gold; coal and lignite; petroleum, natural gas, and asphalt; and nonmetallic minerals other than fuels. The resources of the satellite countries are also examined.

WOODBURY, C., editor. *Urban redevelopment: problems and practices.* (Chicago: Univ. of Chicago Press. 1953. Pp. xvi, 525. $7.50.)

A collection of studies on various aspects of city planning made as a part of Urban Redevelopment Study—a project under the supervision of Public Administration Clear-

ing House, the American Society of Planning Officials, and the National Association of Housing Officials. Part 1, by Allan A. Twichell, is on "Measuring the Quality of Housing in Planning for Urban Redevelopment." Part 2, by William H. Ludlow: "Urban Densities and Their Costs: An Exploration into the Economics of Population Densities and Urban Patterns." Part 3, by Charles S. Ascher: "Private Covenants in Urban Redevelopment." Part 4, by William L. Slayton: "Urban Redevelopment Short of Clearance: Rehabilitation, Reconditioning, Conservation and Code Enforcement in Local Programs." Part 5, by Jack Meltzer: "Relocation of Families Displaced in Urban Redevelopment: Experience in Chicago." Part 6, by Ira S. Robbins and Marian P. Yankauer: "Eminent Domain in Acquiring Subdivision and Open Land in Redevelopment Programs: A Question of Public Use."

Alaska. A reconnaissance report on the potential development of water resources in the territory of Alaska for irrigation, power production, and other beneficial uses, by the U. S. Dept. of the Interior, sponsored by the Bureau of Reclamation. House doc. 197. (Washington: Supt. Docs. 1952. Pp. 287.)

Compilation of laws, executive orders, and regulations applicable to Commodity Credit Corporation, an agency of the United States, as of Oct. 1, 1952. (Washington: Supt. Docs. 1952. Pp. 176, mimeo.)

Compilation of Soil Conservation and Domestic Allotment act, Agricultural Adjustment act of 1938, Federal Crop Insurance act of 1949, Commodity Credit Corporation Charter act, related appropriation items, and miscellaneous laws including amendments as of Jan. 1, 1953. Dept. Agric. handbook no. 49. (Washington: Supt. Docs. 1952. Pp. 174.)

Housing of the nonwhite population 1940 to 1950. Prepared by the Housing and Home Finance Agency. (Washington: Supt. Docs. 1952. Pp. vi, 42. 25¢.)

Investigation of FHA and VA housing programs. Final report from the Subcommittee on Housing of the House Committee on Banking and Currency. (Washington: Supt. Docs. 1952. Pp. 41.)

Missouri—land and water. Report of the President's Missouri Basin Survey Commission. (Washington: Supt. Docs. 1953. Pp. 295.)

The Missouri River basin development program. By the Missouri Basin Inter-Agency Committee. (Washington: Supt. Docs. 1952. Pp. 48.)

The objectives of United States materials resources policy and suggested initial steps in their accomplishment. A report by the chairman of the National Security Resources Board based on the report of the President's Materials Policy Commission. (Washington: Supt. Docs. 1952. Pp. 101.)

Open occupancy in public housing. Prepared by the Public Housing Admin., Housing and Home Finance Agency. (Washington: Supt. Docs. 1953. Pp. v, 30. 20¢.)

Resources: from abundance to scarcity by 1975? Stud. in bus. econ. no. 36. (New York: Nat. Indus. Conf. Board. 1952. Pp. 52.)

The state of food and agriculture: review and outlook 1952. Prepared by the Food and Agriculture Organization of the U.N. Rome, Italy. Oct. 1952. CL 16/2. (New York: Columbia Univ. Press. 1952. Pp. iv, 126. $1.)

Statistical summary 1951—Agricultural Conservation Program. (Washington: Production and Marketing Admin., Dept. of Agriculture. Nov. 1952. Pp. 114.)

A survey of housing research in the United States. (Washington: Div. of Housing Research, Housing and Home Finance Agency. 1952. Pp. 723.)

World food situation 1953. For. agric. circ. WFP-1-55. (Washington: Office of Foreign Agric. Relations. 1953. Pp. 35.)

Years of progress, 1945-1952. (Washington: Dept. of the Interior. 1953. Pp. 195.)

Labor

GOLDSTEIN, J. *The government of British trade unions.* (London: Allen & Unwin. 1952. Pp. x, 300. 25 *s.*)

Knowles, K. G. J. C. *Strikes: a study in industrial conflict—with special reference to British experience between 1911 and 1947.* (New York: Philosophical Library. 1952. Pp. xiv, 330. $8.75.)

Lhomme, J. *La politique sociale de l'Angleterre contemporaine.* (Paris: Presses Univ. de France. 1953. Pp. 518. Fr. 1,800.)

The primary concern is with wages—their relation to cost of living and employment, wages policy, policy with respect to the cost of living—and with employment policy. The period receiving major attention is that since 1938, with particular regard for recent and contemporary aspects of the British economy.

Patel, S. J. *Agricultural labourers in modern India and Pakistan.* (Bombay: Current Book House. 1952. Pp. 172.)

Peck, G. *Emergency disputes settlement.* Library of Congress, Legislative Reference Service staff report to the Subcommittee on Labor and Labor Management Relations of the Senate Committee on Labor and Public Welfare, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 55.)

Pierson, F. C. *Community wage patterns.* Pub. of the Institute of Indus. Relations. (Berkeley: Univ. of Calif. Press. 1953. Pp. xvii, 213. $3.75.)

"The monograph begins with a general examination of the factors bearing on community wage levels and wage structures. This is followed by a discussion of early wage history in the Los Angeles area up to 1940 and then an analysis of Los Angeles wages during the decade of the 1940's. Other chapters deal specifically with those factors which have been most influential in determining the level and pattern of wages in this area . . . at every step in the discussion comparisons are made with wage developments in other communities and in the country as a whole" (from the Foreword).

Ronken, H. O. and Lawrence, P. R. *Administering changes—a case study of human relations in a factory.* (Boston: Grad. School of Bus. Admin. 1952. Pp. 324.)

Shister, J. and Hamovitch, W. *Conflict and stability in labor relations: a case study.* (Buffalo: Dept. of Indus. Relations, School of Bus. Admin., University of Buffalo. 1952. Pp. 69.)

Smulders, M. F. *Inkomensverdeling en werkgelegenheid.* (Leiden: H. E. Stenfert Kroese N. V. 1952. Pp. v, 174. f. 9.75.)

Steiner, P. O. and Goldner, W. *Productivity.* (Berkeley: Inst. of Indus. Relations, Univ. of Calif. 1952. Pp. x, 60. 25¢.)

Building America's health: a report to the President. By the President's Commission on the Health Needs of the Nation. (Washington: Supt Docs. 1952. Pp. 80.)

Demographic yearbook—1952. U.N. pub. no. 1953. XIII.I. (New York: Columbia Univ. Press. 1953. Pp. 518. $7.50.)

Needed changes in the old age and survivors' insurance program. (Washington: Council of State Chambers of Commerce. 1952. Pp. 18.)

Pensions in the United States. A Nat. Planning Assoc. study prepared for the Joint Committee on the Economic Report, 82nd Cong., 2nd sess. (Washington: Supt. Docs. 1952. Pp. 106.)

Unclassified Items

BALL, W. M. *Nationalism and communism in East Asia.* (Melbourne: Univ. Press. New York: Cambridge Univ. Press. 1953. Pp. v, 210. $4.50.)

Necessarily brief treatments of political movements in ten different countries with some attention to the economic and social background in each case.

DARBY, H. C. *The Domesday geography of eastern England.* (New York: Cambridge Univ. Press. 1953. Pp. xiv, 400. $11.)

This is the first of six volumes, each to be on the medieval geography of one section of England as revealed by the Domesday Book.

GINZBERG, E., and BRAY, D. W. *The uneducated.* (New York: Columbia Univ. Press. 1953. Pp. xxv, 246. $4.50.)

HOLLAND, W. L., editor. *Asian nationalism and the West.* A symposium based on documents and reports of the Eleventh Conference, Institute of Pacific Relations. (New York: Macmillan. 1953. Pp. viii, 449. $5.)

KOHN, H. *Pan-Slavism: its history and ideology.* (Notre Dame, Ind.: Univ. of Notre Dame Press. 1953. Pp. ix, 356. $6.25.)

KUHN, H. W. and TUCKER, A. W., editors. *Contributions to the theory of games,* vol. II. Annals of mathematics stud. no. 28. (Princeton: Princeton Univ. Press. 1953. Pp. viii, 395. $4.)

MCAULIFFE, W. R. *Modern Asia explained.* (New York: Philosophical Library. 1952. Pp. viii, 163. $3.25.)

"This book is a modest attempt to give in simple language some account of the development and aspirations of the Asiatic states which have recently freed themselves, or been freed, from Western colonization and economic penetration. Some effort has been made to sketch the historical, social, and religious backgrounds to this development."

McDougall, F. L. *Food and population.* Internat. Conciliation, no. 486. (New York: Carnegie Endowment for Internat. Peace. 1952. Pp. 47.)

Scott, J. F. and Lynton, R. P. *The community factor in modern technology.* Tensions and technology ser. UNESCO. (Washington: UNESCO Relations Staff, Dept. of State. 1952. Pp. 171.)

Weschler, I. R. and Brown, P., editors. *Evaluating research and development.* Annotated proceedings of Conf. of Research Administrators at Univ. of Calif., Los Angeles, May 10, 1952. (Los Angeles: Institute of Industrial Relations, Univ. of Calif. 1953. Pp. 103. $1.65.)

White, R. C. *These will go to college—a study of future demand for admission to college by secondary school graduates in the Cleveland-Akron-Lorain area.* Spons. by the Cleveland Foundation. (Cleveland: Western Reserve Univ. Press. 1952. Pp. xvii, 108. $2.75.

Benefit financing. Pt. II, *Unemployment insurance in Montana.* Prep. by Unemployment Compensation Commission, Helena, Montana, and Bureau of Bus. and Econ. Research, Montana State Univ. (Missoula: Montana State Univ. 1951. Pp. 174.)

Committee for Economic Development annual report 1952. Prepared by the Research and Policy Committee. (New York: Committee for Econ. Development. 1953. Pp. 46.)

Economic aspects of higher education in New York State. Prepared by the Student Economics Society of Champlain College. (Plattsburgh: Dept. of Economics, Champlain College. 1953. Pp. 56, mimeo.)

Education in a technological society. Tensions and technology ser., UNESCO. (Washington: UNESCO Relations Staff, Dept. of State. 1952. Pp. 73.)

Register of research in the social sciences in progress and in plan and directory of research institutions. (London: Cambridge Univ. Press, for the Nat. Inst. of Econ. and Soc. Research. 1952. Pp. iv, 188. 15 *s.*)

Social Science Research Council annual report, 1951-1952. (New York: Social Science Research Council. 1953. Pp. 73.)

Theses in the social sciences: an international analytical catalogue of unpublished doctorate theses, 1940-1950. Unesco pub. (New York: Columbia Univ. Press. 1953. Pp. 236. $1.25.)

NOTES

A nominating committee consisting of M. M. Bober, Edward S. Shaw, George W. Stocking, George W. Taylor, Willard L. Thorp and John H. Williams, chairman, has submitted the following slate of nominees for 1954 officers of the American Economic Association:

President: Simon S. Kuznets, University of Pennsylvania

Vice President:

Roy Blough, Director, Department of Economic Affairs, United Nations
William J. Fellner, Yale University
Jacob Marschak, University of Chicago
Arthur Smithies, Harvard University

Executive Committee:

Moses Abramovitz, Stanford University
Evsey D. Domar, John Hopkins
Norman S. Buchanan, University of California
George J. Stigler, Columbia University

Representative of Social Science Research Council:

D. Gale Johnson, University of Chicago

The annual meeting of the Association will be held at the Hotel Statler, Washington, D.C., December 28-30, 1953. The meeting is to be held jointly with allied social science associations. Thus far the Econometric Society, the American Finance Association, the Economic History Association, the American Statistical Association and the Industrial Relations Research Association have indicated their intention of meeting at the same time in Washington.

Deaths

Herbert F. Fraser, professor of economics at Swarthmore College, died February 9, 1952.

Donald J. Hay, instructor in marketing at the University of Illinois, died November 1, 1952.

Frederick E. Lee, of the department of economics, University of Illinois, died September, 1952.

Earl A. Saliers, of Louisiana State University, died December 23, 1953.

Retirements

Clyde B. Aitchison, after serving almost thirty-five years as an Interstate Commerce Commissioner.

John D. Black, as Henry Lee Professor of Economics, effective July, 1953.

Theodore T. Bullock, professor of economics and business law, College of Business Administration, University of Nebraska, February, 1953.

Harry W. Cordell, associate professor of marketing, the Ohio State University, June, 1953.

William H. Spencer, Hobart W. Williams Distinguished Service Professor of Government and Business, effective September, 1953.

Thomas L. Kibler, professor of transportation at the Ohio State University, June, 1953.

Appointments and Resignations

Robert Agnew has been appointed assistant professor of industry in the School of Business Administration, University of Pittsburgh.

A. Anastassiades has been appointed instructor in economics in the School of Business Administration, University of Pittsburgh.

Edward A. Anderson has been appointed instructor in marketing in the Wharton School, University of Pennsylvania.

Arthur G. Auble, of Northwestern University, has been appointed associate professor of business statistics at Claremont Men's College.

Edwin H. Baldridge has been promoted to assistant professor of accounting in the School of Business Administration of the University of Pittsburgh.

Claude D. Baldwin, formerly in the Bureau of the Budget, is now economist in the Office of the Secretary of Defense.

William J. Baumol, of Princeton University, is visiting professor of economics at the University of California, Berkeley, in the spring term.

Edward G. Bennion, director of the General Economic Division of the Standard Oil Company of New Jersey, will be visiting professor of economics at the Massachusetts Institute of Technology in 1953-54.

William Beranek has been appointed lecturer in finance in the School of Business Administration, University of California, Los Angeles.

Hilary R. Beth has been appointed instructor in management in the College of Business Administration, Tulane University.

R. A. Blackwood has been appointed instructor in business administration at Louisiana State University.

Arthur I. Bloomfield, senior economist of the Federal Reserve Bank of New York, has returned from the Associated States of Indochina where he served as economist for a Mutual Security Agency mission.

Robert W. Bradbury is resuming his duties at the University of Florida after a year in foreign service with the Department of State.

Robert B. Buchele has been appointed assistant professor of personnel management and industrial relations at the University of California, Los Angeles.

Arthur F. Burns, of Columbia University, has been appointed to the Council of Economic Advisers to the President.

John M. Clark was appointed special lecturer in the department of economics, Columbia University, upon becoming professor emeritus in February 1953.

Edward Coen, of the London School of Economics, was visiting lecturer at the University of Minnesota in the spring quarter.

Gerhard Colm, chief economist of the National Planning Association, has been in Korea consulting on matters relating to rehabilitation and in India consulting with Indian leaders concerned with national economic planning.

Edward J. Cook has been promoted to assistant professor in the School of Business, Fordham University.

C. H. Donovan has been appointed head of the department of economics in the College of Business Administration of the University of Florida.

Frederick Downs, of the University of Wisconsin, has accepted an appointment as research associate with the University of Kentucky Bureau of Business Research.

James S. Duesenberry has been promoted to associate professor of economics at Harvard University.

James S. Earley, of the University of Wisconsin, has been granted a leave in 1953-54 to accept a Carnegie Foundation grant in connection with the Directed Studies Program at Yale University.

Joseph B. Eisenberg has been appointed instructor in industry in the Wharton School, University of Pennsylvania.

Philip Elkin has been appointed instructor in insurance in the Wharton School, University of Pennsylvania.

Solomon Fabricant has been appointed deputy director of research at the National Bureau of Economic Research.

Gerald J. Feldman has been appointed instructor in industry in the Wharton School, University of Pennsylvania.

George N. Francis has been promoted from assistant professor to associate professor of accounting at Los Angeles State College of Applied Arts and Sciences.

Irwin Friend has been appointed lecturer in finance at the Wharton School, University of Pennsylvania.

Wytze Gorter, of the University of California, Los Angeles, has been awarded a Carnegie

Research Fellowship by the Council on Foreign Relations, at whose New York headquarters he will conduct research in 1953-54.

Daniel H. Gray has been appointed assistant professor of economics at Tufts College for the year 1953-54.

Walter Heim has been appointed assistant professor of accounting in the School of Business Administration, University of Pittsburgh.

Richard M. Heins has been appointed lecturer in insurance in the School of Business Administration, University of California, Los Angeles.

Charles H. Hession has been promoted from assistant professor to associate professor of economics at Brooklyn College.

Werner Z. Hirsch, of the University of California at Berkeley, has been appointed assistant professor of economics at Washington University, St. Louis.

Thomas P. Hogan has been appointed instructor in economics in the School of Business Administration, University of Pittsburgh.

Carl Iversen, of the University of Copenhagen, has been appointed visiting professor of political economy at the Johns Hopkins University for the February 1954 term.

C. Hayden Jamison has been appointed chairman of the department of economics and finance at Beloit College in the absence of Dr. Lewis Severson.

Eugene E. Jennings has been appointed assistant professor of industry at the Wharton School, University of Pennsylvania.

John E. Jeuck has been promoted to professor of marketing and succeeds Garfield V. Cox as dean of the School of Business, University of Chicago.

Michael J. Jucius, now at the University of Turin, Italy, will resume his duties as professor of personnel at the Ohio State University in the autumn quarter.

K. William Kapp has been promoted from associate professor to professor of economics at Brooklyn College.

Charles P. Kindleberger, of the Massachusetts Institute of Technology, will be on leave in 1953-54 to conduct research, using the facilities of the Economic Commission for Europe at Geneva, Switzerland, on a grant from the Merrill Foundation for Advancement of Financial Knowledge.

Walter Kirk has been appointed assistant professor of finance in the School of Business Administration, University of Pittsburgh.

John P. Lewis has been appointed associate professor of business administration in the School of Business, Indiana University.

E. E. Liebhafsky has accepted an appointment as assistant professor of economics at Pennsylvania State College.

Bernard S. Logan has been appointed assistant professor of economics in the School of Business Administration, University of Pittsburgh.

Clarence D. Long, of Johns Hopkins University, has been visiting professor of economics at Columbia University for the spring term.

David L. Lutin, formerly research associate at Massachusetts Institute of Technology, is now an economist in the Office of the Administrator, Housing and Home Finance Agency, Washington, D.C.

Wilfred Malenbaum has joined the staff of the International Studies group at Massachusetts Institute of Technology.

C. Arnold Matthews has returned to the University of Florida after having served with the Armed Forces since 1951.

Dan M. McGill has been appointed associate professor of insurance in the Wharton School, University of Pennsylvania.

Edmund A. Mennis has resumed his duties as security analyst on the research staff of the Wellington Fund in Philadelphia after service in the Military Air Transport Service.

Hermann Meyer-Lindenberg, of Bogota, Colombia, has been appointed visiting professor of economics for the spring term at the University of California, Berkeley.

Raymond F. Mikesell will be on leave from the University of Virginia August to December this year to serve as visiting professor at the National War College.

Ralph A. Nittinger has been appointed instructor in insurance at the Wharton School, University of Pennsylvania.

Thaddeus J. Obal has resigned from the Congressional Joint Committee on the Economic Report to accept a position as economic analyst in the Ford Motor Company.

John F. Orchard has been appointed acting dean of the Graduate School of Business, Columbia University.

Raymond R. Orie has been appointed instructor in accounting in the School of Business Administration, University of Pittsburgh.

Grant M. Osborn has been appointed instructor in insurance in the Wharton School, University of Pennsylvania.

A. R. Oxenfeldt has resigned as associate professor of economics at the City College.

Irving Pfeffer has been appointed instructor in insurance at the Wharton School, University of Pennsylvania.

Karl Polanyi has terminated his services with Columbia University as visiting professor of economics as of February 1953.

Hoyt Price is now second secretary in the American Embassy at Saigon.

John M. Rathmell has been appointed lecturer in marketing at the Wharton School, University of Pennsylvania.

Richard Reed has been appointed instructor in economics at Wheaton College.

George F. Rohrlich has been appointed chief of the Division of Actuarial and Financial Services, Unemployment Insurance Service, Bureau of Employment Security, Department of Labor.

Sam Rosen has been appointed assistant professor of economics at the University of Delaware.

Hilda Rosenbloom has returned to Wellesley College as assistant professor of economics.

James H. Rossell has been promoted to assistant professor of accounting in the School of Business Administration, University of Pittsburgh.

Simon Rottenberg has been appointed visiting assistant professor and research associate at the Research Center in Economic Development and Cultural Change and Industrial Relations Center, University of Chicago.

Eugene Rotwein has been granted a leave of absence from the University of Wisconsin in 1953-54 to accept a Carnegie Foundation grant in connection with the Contemporary Civilization Program at Columbia University.

Francisco R. Saenz, formerly attaché to the Economic Division of the Mexican Embassy in Washington, is now with the foreign department of the Manufacturers Trust Company, New York, N.Y.

David J. Saposs, who has been special adviser to the director of the European Labor Division of the Mutual Security Agency in Paris, has returned to his post as special assistant to the Commissioner of Labor Statistics, Department of Labor.

Richard Scheuch has been promoted to assistant professor of economics at Trinity College.

Morton J. Schussbeim, economist with the Cleveland City Planning Commission, has been visiting lecturer in urban land economics at Western Reserve University in the spring term.

Frederick A. Schwarz has been appointed assistant professor of accounting in the School of Business Administration, University of Pittsburgh.

Carlo Sciffo has been appointed instructor in economics in the School of Business Administration, University of Pittsburgh.

Robert W. Semenow has been promoted to associate professor of real estate in the School of Business Administration, University of Pittsburgh.

Irving A. Sirken, formerly of Williams College, has accepted a position as chief of Industrial Analysis and Program Evaluation, Economic Development Administration, San Juan, Puerto Rico.

George R. Taylor, of Amherst College, has been visiting professor of economics at Columbia University in the spring term.

Reed Tripp, of the University of Wisconsin, has accepted a position with the University of Kentucky Bureau of Business Research.

Randall W. Tucker has been promoted to assistant professor of economics at Trinity College.

Ralph Turvey, of the London School of Economics and Political Science, has been appointed visiting lecturer at the Johns Hopkins University for the October 1953 term.

Lloyd Ulman, of the University of Minnesota, has been awarded a three-year faculty fellowship by the Social Science Research Council.

Arthur R. Upgren has been appointed dean of the Amos Tuck School of Business Administration, Dartmouth College.

Daniel C. Vandermeulen will return to Claremont Men's College in September as associate professor of economics.

Royal S. Van de Woestyne has assumed the dual position of associate dean and dean of students of the School of Business, University of Chicago.

Charles W. Voris has resigned from Washington State College to join the staff of Los Angeles State College of Applied Arts and Sciences, as assistant professor of industrial management.

Louis A. Werbaneth has been appointed instructor in accounting in the School of Business Administration, University of Pittsburgh.

Robert H. Wessel has been promoted to assistant professor of economics at the University of Cincinnati.

Frank N. Willets has been appointed assistant professor of accounting in the School of Business Administration, University of Pittsburgh.

Max A. Woodbury has been appointed associate professor of statistics in the Wharton School, University of Pennsylvania.

William Woodruff, of Nottingham University, Nottingham, England, has accepted an appointment as associate professor of economics at the University of Illinois, effective September 1953.

H. Edward Wrapp has been appointed associate director of the Executive Program in the School of Business, University of Chicago.

Bertram W. Zumeta has been appointed instructor in statistics in the Wharton School, University of Pennsylvania.

VOLUME XLIII SEPTEMBER, 1953 NUMBER FOUR PART I

THE THEORY OF THE OFFSET FACTOR: THE IMPACT OF LABOR DISPUTES UPON COAL PRODUCTION

By C. LAWRENCE CHRISTENSON*

Although bituminous coal mining in the United States contains only a small fraction of the industrial working force, it was responsible for a larger volume of dispute time losses than any other single industry during the two decades beginning in 1930. Moreover, in no other single industry has the possibility of interference with production by labor disputes generated as much showing of public alarm as in the case of bituminous coal.[1] Indeed at times, the power of this industry to develop

* The author is professor of economics at Indiana University.

Even a condensed list of names of the many persons to whom the author is indebted for help in preparation of this article must include: W. H. Young of the Bureau of Mines, Loretta Nolan and Ann Herlihy of the Bureau of Labor Statistics, Walter Slifer of the Bituminous Coal Institute, John L. Lewis and W. A. Boyle of the United Mine Workers, Osmond Harline of the University of Utah and Mrs. Suzanne Clauser, secretary in the Division of Economic Research at Indiana University. Professors Sterling McMillan of Western Reserve University, Clarence Efroymson of Butler University, Roland Davis, Arthur Schweitzer, William Andrews, and George Horwich who are colleagues at Indiana University, have all been good enough to read an original draft of the manuscript and offer helpful criticisms. Responsibility for the article in its final form, of course, must rest with the author.

[1] "Taking man-days idle as a rough measure of the extent of strike activity, the figures indicate that from 1927 to 1932 the man-days idle due to strikes in the coal mining industries averaged 61 per cent of man-days idle in all industries combined; . . . for the period, 1933 to the middle of 1946 . . . the man-days idle due to strikes in the coal industries averaged 27 per cent of the man-days idle in all industries combined." *Economic Power of Labor Organizations; Hearings,* July 21-August 2, 1949, Committee on Banking and Currency, U.S. Senate, 81st Congress (Washington, D.C., 1950), Part I, p. 278. Hereafter cited: *EPLO Hearings.* Warren states that for 1914-49, classification of news accounts of "reported strike situations" shows 23.4 per cent of those in the New York Times and 21 per cent of those in the Los Angeles Times were in coal mines. Railroad and airline strike situations were slightly more numerous (23.9 per cent) in the Los Angeles Times, but apart from that, in no other industry did strikes enlist as much newspaper coverage as in coal mining. Edgar L. Warren, "Thirty-Six Years of National Emergency Strikes," *Indus. Lab. Rel. Rev.,* Oct. 1951, V, 3-15.

political and journalistic heat has seemed greater than its capacity to furnish the basic fuel for the American industrial economy. In the policy controversies of the war and postwar years there was an appreciation of the national importance of the bituminous coal industry, but there was not always an equal recognition of its peculiar economic characteristics. The public press often attributed the operating pattern of the industry to the personalities of particular individuals without much allowance for the physical fact that coal mining is an industry of varying seams, faults, shafts, strips and product volatility. Numerous actions for dealing with strikes in this industry, and indeed in others, were taken; and the cry of "national emergency" whenever a stoppage was threatened became a cliché without much specific meaning.

It is the purpose of this article to develop a theory of the impact of disputes on production particularly applicable to the bituminous coal industry, but which may also outline some features that are of broader significance. Such a theory will not furnish a solution for national emergency strikes, but it may furnish guidance for determining when an emergency is present. In social as in medical science, it might be well for diagnosis to precede surgery. Even complete success in microscopic measurement of the influence of labor disputes upon coal production in the eighteen years, 1933-1950, will do no more than create a "small window that looketh out upon a great world." That window will have more than one opaque pane, and some mullions badly fitted, waiting for other more skillful efforts with better tools and more nearly pure materials to present a clearer view.[2]

I. *The Production and Dispute Record in Bituminous Coal 1933-1950*

A synoptic view of the relation of dispute time losses to the monthly output of coal is presented in the chart entitled "Monthly National Use Production and Disputes Man-Day Losses in Bituminous Coal 1933-50." The continuous line of monthly production calculated from the "Weekly Coal Reports" of the Bureau of Mines is the calendar-adjusted, total monthly output after the substraction of exports, bunker fuel, and coal used at the mines. These subtractions are based on the assumption, only partially valid, that such items involve commitments for coal that cannot be made available for internal consumption in the national market. The broken line on the chart records the number of man-days lost by labor disputes in the corresponding months as shown

[2] The Division of Economic Research at Indiana University has in process other studies on the economics of the coal industry, and this article is only a portion of a larger research plan.

in the file records of the Bureau of Labor Statistics.[3] Although a little cumbersome, it seems accurate to change the Bureau's terms of "man-days idle" in "work stoppages" to "disputes man-day losses."[4] This is the expression I have chosen to use throughout, except when considering the more general matter of strikes or lockouts without reference to specific monthly measurement, when I shall use the term "disputes time losses."

The presentation of the BLS disputes time loss record, without adjustment of any kind, against the background of a reduced and calendar-adjusted figure of total coal production, may seem to exaggerate the force of dispute time losses. However, the substraction of external items results in a smaller rate of tonnage loss per man-day of disputes than may be the actual case. Nevertheless, regarding these external items as firm commitments avoids overstatement in the amount of coal available for national use, and it cannot be said that the nature of any "emergency" has been minimized. In the calculated impact of dispute time losses "emergencies" are taken in full seriousness and perhaps even exaggerated. This is the reason adjustments are made in the production record even though I find no way of making similar modifications in the dispute time loss figures.

The scale for the production line, shown on the left side of the chart, is in millions of tons; while that for dispute time losses, on the right, is in millions of man-days. For convenient reading, guide lines have been drawn at the 40 million-ton monthly production level and at the level of four million man-day dispute time losses.

[3] The Bureau of Labor Statistics records "all known stoppages arising out of labor management disputes, involving six or more workers and continuing a full day (or shift), or longer. . . . Figures . . . on 'man-days idle' cover all workers made idle for one shift or longer in establishments directly involved in these stoppages." This statement or one similar will be found in any annual issue of the bulletins entitled "Analysis of Work Stoppages." For example, see Bull. No. 1090, U.S. BLS (Washington, D.C., 1952).

In the years while the Bureau of Mines also made an independent review of strikes in coal mining, the total time lost figures were usually somewhat larger than those reported by the Bureau of Labor Statistics. This may have been due in part to broader coverage but also may have been due to difference in definitions used. The Bureau of Mines classified its figures under the heading "Strikes, Suspensions and Lockouts," which might well include some stoppages omitted by BLS as not being "suspensions due to disputes." A memorandum of the Bureau of Labor Statistics recognized the difference in the records of the two agencies thus: in 1942, "the Bureau of Labor Statistics set up a new cooperative arrangement with the Solid Fuels Administration which resulted in the receipt of additional strike leads. When this agency went out of existence, cooperative arrangements were made with other agencies. Prior to this time, undoubtedly many of the small, short strikes were missed."

[4] The expression, work stoppage, seems to me less desirable than disputes loss, since it may apply to secondary stoppages occurring in other establishments and also to the many interruptions of production not directly or indirectly concerned with a labor dispute in spite of the Bureau's warning that this is not so intended.

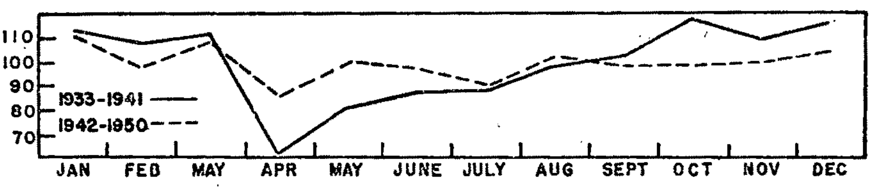
The chart is divided into two sections, each covering a nine-year period of 108 months. Certain obvious points of the relationship between disputes time losses and production in these two periods are therefore easily compared. For the 1933-1941 period national use production is below the 40 million ton guide line in 87 months and above it for the other 21 months. In 1942-1950, however, there are only 19 months when production falls below the guide line and 89 months when it is considerably above. Indeed in 70 of these 89 months, output is between 40 and 50 million tons and in the other 19 it even passes the 50 million ton level. The annual seasonal variation and general upward trend, broken only by the 1938 recession, is apparent for the 1933-1941 period. In contrast, the disappearance of the rising trend and the reduction of seasonal influences[5] is evident for the later period. By 1942, the production line, having reached a much higher level, tends to remain there except during months of large dispute losses, until it is finally pushed downward by the 1949 postreconversion slump.

In dealing with the dispute record in the bituminous coal industry it is both sensible and convenient to take the figure of 300,000 monthly man-day losses as a bench mark to separate minor from major dispute months. I use the term "minor dispute month" to mean a month with dispute man-day losses of 300,000 or less, and the expression "major dispute month" to refer to those months with working time losses in excess of such amounts. For an industry with approximately 400,000 production workers this bench mark would be equivalent to a loss of one day of working time for 75 per cent of the force. Similarly, the figure of four million man-day losses which I have used for the guide line in the chart might represent a ten-day monthly time loss for an entire working force of 400,000 employees.[6]

While the number of months with less than 300,000 dispute man-day losses are not classified in detail, it should be stated that there was no

[5] Comparative indexes of seasonal variation appear as follows:



Seasonal Indices of U.S. Bituminous Coal Production
(Monthly Averages as Percent of Annual)

[6] Calculations based on the average monthly number of production workers attached to bituminous coal mining for each year as reported in the BLS Handbook of Labor Statistics (Washington, D.C., 1950), give annual average figures of 416,000 for 1933-1941 and 393,000 for the later nine-year period.

month during the eighteen years without some time loss from disputes. Partly because of the scale used, the chart line, representing minor dispute losses in certain months in 1933-1941, has to run so close to the base as to be almost imperceptible. Also, some small local disputes may have escaped recording in the earlier years.

The chart easily reveals that major dispute months involved time losses larger in magnitude and more numerous in 1942-1950 than in the nine earlier years. An exact count shows that 1942-1950 contained 27 such months, while there were only 14 in the 1933-1941 period. If these major dispute months are broken down into smaller classifications, only four months prior to 1942 involved dispute time losses of a million man-days or more, while there were 17 such months during the nine years following. The record for only two months during 1933-1941 crosses the four million man-day guide line on the chart, while that for five different months passed this mark after 1942.

The division of the eighteen-year record into two periods of nine years each has been based on several considerations. Not the least of these has been the special significance of the year 1941 as the demarcation line for the first period. From the ashes of the 'twenties, under the impetus of the NRA in 1933, the phoenix of unionism in the coal industry began its resurgence. It reached maturity only at the close of 1941. Then it was that the formal inclusion of the industrial-consumer owned mines (*i.e.*, "captive mines") within the orbit of unionism made the recognition of the United Mine Workers of America (hereafter U.M.W.) extend through about 80 per cent of the industry.[7]

[7] The 80 per cent figure is an approximation of the actual facts. The campaigns of the rival Progressive Mine Workers of America in West Virginia, Pennsylvania, Kentucky, and Kansas had come to unsuccessful ends by 1940, and that organization was then confined to representation in the Illinois mines. Its membership by 1950 was between eight and ten thousand in mines producing about 25 per cent of the Illinois tonnage. For the only comprehensive study of the P.M.W. see Harriet D. Hudson, *The Progressive Mine Workers of America: A Study in Rival Unionism* (University of Illinois Bull. Ser. No. 73, Urbana, 1952). Since the 1947 withdrawal of the U.M.W. from the A.F. of L., membership figures have not been published, but the Welfare and Retirement payments of 128 million dollars in 1951 represent payments on 82.5 per cent of the tonnage produced in that year, while payments for the 12 months ending July 1, 1949, covered 76 per cent of the tonnage. Important coal producing states from which welfare payments covered considerably less than 60 per cent of state tonnage were Kentucky and West Virginia. The possibility of both late and advance payments prevents such calculations from being precise measurements. See *U.S. News and World Report*, May 2, 1952, p. 59; *Chronology; U.M.W. Welfare and Retirement Fund*, (U.M.W., Washington, D.C., 1950), p. 14. Also, see Testimony of Josephine Roche, in *EPLO Hearings*, Part I, p. 194 and pp. 141, 143, 146, and 518. Daugherty and Parrish probably overstate the membership of U.M.W. as being 90 per cent of the bituminous mine workers in 1951. However, the calculation on the basis of current tonnage covered by welfare payments is not parallel with estimates of union membership in the working force. Many men may retain union membership after retirement, or when working only part-time, and, moveover, output per

However, the complete acceptance of unionism in the consumer-owned mines since 1941 has tended to cover up the fact that significant portions of the commercial branch of the industry have remained outside the unionized framework. Probably, if the commercially sold production is taken alone, only about 75 per cent of tonnage has been from mines operating under U.M.W. agreements.

It is sometimes claimed, and it is certainly implied in the declarations of policy of both the National Labor Relations Act and of its successor, the Labor Management Relations Act, that when organizational strife in the establishment of unionism is over, losses in working time due to labor disputes may be expected to decrease. For the bituminous coal industry, at least, such claims are not well founded. The simple review of the actual record shows clearly that dispute time losses since 1942 have been vastly greater than in the earlier years of ascendancy of unionism before its widespread acceptance had been re-established.

This finding, significant though it may be, is not the most striking revelation growing out of the review of the production and dispute record. The truly surprising discovery, for purposes of this study, is the demonstrated fact that the greater dispute time losses after 1942 were accompanied by output from the coal mines exceeding that of all previous records. No other nine-year period in the entire history of coal mining in the United States can match the record of 1942-1950 either for dispute time losses or for production. It is this phenomenon which demands explanation.

II. *The Theory of the Offset Factor*

Two Forms of Impacts of Dispute Time Losses on Production

A layman's view of the relation of production to dispute time losses might be: "Coal miners, when they work, produce coal don't they? Then when they walk out or are locked out, they don't mine coal and therefore output falls by the amount that would have been produced if the men had remained at work." It seems apparent that this simple view, if not entirely wrong, is still considerably less than half the truth.

An explanation of the actual record of the relation between disputes time losses and production requires the development of a new theory which I call "the theory of the offset factor."[8] The offset factor is

man in some of the nonunion mines may be higher than in unionized mines. See Carroll R. Daugherty and John B. Parrish, *The Labor Problems of American Society* (Boston, 1952), p. 570.

[8] Awareness of need for such a theory is indicated in the writings of others. Thus George Taylor writes concerning the BLS disputes figures, "These data, which constitute a census

merely a label for those forces which mitigate the impact of dispute time loses upon production. The identification of these forces is difficult and needs development in detail. It is assumed that labor disputes represent real differences between representatives of employees and management officials which are, in part, causal forces that influence the volume of production. This is certainly implicit in the layman's view of disputes and is also the view expressed in many of the Congressional proposals for dealing with national emergency strikes. At present, I do not challenge this assumption, although it probably is not universally valid. A publicly declared labor dispute might be a result of a particular production level as well as the cause of it. Moreover, such a dispute may be less of a contest between management and labor than it is an expression of different views of industry control.

Whether labor disputes generate production changes or are themselves generated by the level of production, they are in any case immediate short-run phenomena. A mine while closed down during a labor dispute does not produce coal. This much is about all there is in the layman's view that is obviously correct. But the importance of this observation lies in its emphasis on the immediacy of the relation between a dispute and output, not in its usefulness for measurement of the full strength of the impact of the dispute.

The full effect of dispute time losses on production volume is by no means simple, nor is it uniform for all industries. I do not pretend to identify all the different pertinent industrial circumstances, but a few that seem generally important may be mentioned. In considering the impact of any dispute time loss it is necessary to observe the character of the product as well as the nature of the production process, and more specifically the importance of labor to current output. Coal is a source of industrial power, but so too is electricity generated by hydro-electric plants. Conceivably, however, a labor dispute which resulted in the walk-out of the entire mechanical force of a hydro-electric station, for say, twenty-four hours, might make no difference whatever in the

of strikes, are frequently presumed to be an adequate index of the severity of costs of strikes in their impact on national output, production, or the effective prosecution of the war. No such presumption is justified. Many strikes result in no net loss in working time or production since hours that would otherwise have been idle are worked. Other stoppages in the critical component may have tremendous effects upon total production. It is simply impossible to indicate the effect of industrial disputes from simple enumeration." "Labor's No-Strike Pledge—A Statistical Review," *Yearbook of American Labor* (New York, 1945), p. 140. Milton Friedman states suggestively: "In many cases, so to speak, unions are simply thermometers registering heat rather than furnaces producing the heat." In D. M. Wright, *The Impact of the Union* (New York, 1951), p. 222, also p. 205. For an argument which even more closely parallels that developed here see Lloyd G. Reynolds, *Labor Economics and Labor Relations* (New York, 1949), p. 307. My own study shows that some points mentioned by Reynolds are of much broader applicability than he allows.

amount of electricity delivered. Similarly an oil refinery might continue regular production for a day with only a skeleton crew. On the other hand, readers who want today's news will not get it by the delivery of a paper which is printed next month; nor will an audience that wants entertainment tonight get it if the cast and stage crew walk out with the promise of returning next week.

The bituminous coal mining industry is not a continuous process industry that might operate automatically without any labor for a short time; nor in the major dispute months, are we confronted with temporarily endurable defection of small portions of a labor force. Neither, however, is coal a commodity that is consumed concomitantly with its production so that any temporary stoppage means a complete loss of the service that might have been forthcoming had there been no dispute. Measured by dollar cost of production, bituminous coal is from 50 to 70 per cent labor; and major time losses are almost certainly associated with the termination date of national or district agreements. They usually apply to the entire productive labor force of the firms involved in the dispute. The illustrations mentioned are theoretical possibilities, but their importance here is simply to make the character of the coal industry stand out in sharp relief. Viewed from the side of the production process, dispute time losses in the coal industry present a real possibility of bringing about reduction in total output.[9]

The impact of any dispute that results in reducing total output below levels that would have prevailed had that dispute not occurred I choose to label "detractive." However, this type of impact is not the only kind associated with dispute time losses.

Approaching the question from the demand side, we may consider a situation when the total demand for coal is decreasing. During such a period representing a downswing in the business cycle, coal output will be falling due to a shrinkage in consumer demand requirements. A dispute time loss arising under these circumstances, if spread broadly enough over a large portion of the industry, may affect the location of the output shrinkage even though it does not change its absolute quantity. It is this power to influence the location of an already shrinking output that I call the "distributive" impact of dispute time losses.

This distributive impact is often overlooked because of the mistaken assumption that labor union action tends to be limited only to efforts to

[9] Preliminary examination of materials suggests that coal may be considered as having a relatively inelastic demand schedule not subject to rapid shifts in position. There are, however, some notable qualifications, as in the case of certain steam electric generating plants that maintain auxiliary oil burning equipment which may be brought into use quickly if there is distress selling of fuel oil. Over longer periods there are still broader possibilities of reliance upon substitutes. For the present these long-run forces are neglected.

improve current working conditions for members as individuals. But in a period of shrinking demand, falling production is almost certain to bring increasing unemployment, especially in an industry where wages bulk large in total costs. The simple fact that employment and production are two different sides of the same coin must therefore mean that any union action designed to influence the manner in which unemployment is to spread must also influence the distribution of the volume of production.

This classification of dispute impacts recognizes that even the potential effect of dispute time losses on production may vary depending upon the conditions of demand existing when the dispute occurs. The detractive impact, which is the kind that seems to be most common in the layman's mind, may not exist at all under conditions of falling demand, although a distributive impact may still be present.

The clearest illustration of the distributive impact in the coal industry occurs during seasonal recessions. Such timing was almost automatic and regular in the coal industry during the period 1933-1941, because of the practice of having union wage agreements terminate in April. Speaking broadly, the effect of this practice is to synchronize the possibility of prolonged stoppages over failure to reach agreement with normally anticipated seasonal reduction in demand. A generally supported walkout would merely spread the adjustment to shrinking demand throughout all mines. Such a dispute, however, may be charged with contributing to an aggregate production shrinkage even though the apparent detractive impact certainly would be spurious.

This situation presents a serious dilemma from which I have found no adjustment of the statistical record that provides a satisfactory solution. Especially in so far as the bituminous coal industry is concerned, it cannot be said with confidence that dispute time losses are strictly independent forces divorced from cyclical and seasonal variations.[10] Whether the dispute time losses have any real distributive impact under these circumstances, depends upon how extensively the dispute spreads through the industry.

[10] Customarily it seems to be assumed that strikes are irregular factors in time series. Thus one well-known text in economic statistics discussing adjustments for various movements in time series, reports: "The scheme most commonly employed for this purpose involves a fourfold classification attributing variations in time series to changes in the seasons, to the business cycle, to secular growth or decline, and to numerous irregular influences such as wars, droughts, and *strikes*." (Italics mine.) D. W. Paden and E. F. Lindquist, *Statistics for Economics and Business* (New York, 1951), p. 170. Unfortunately for simplicity of statistical procedure, strikes in the coal industry cannot be treated as merely "irregular influences." Even in a broader economic setting than a single industry the careful study by Rees suggests that strikes may be a part of business cycle movements rather than "irregular influences." Albert Rees, "Industrial Conflict and Business Fluctuations," *Jour. Pol. Econ.*, Oct., 1952, LX, 371-82.

Both the detractive and distributive impact of dispute time losses are positive elements that threaten to influence the character of production. This does not mean, however, that the threatened influence is necessarily disastrous for aggregate output or that distribution of output among firms is actually modified. Both such impacts may be mitigated, perhaps even absorbed completely, through the operation of the offset factor. Its operation may vary considerably, and these variations will be examined after the general nature of the offset factor has been set forth.

The Offset Factor: Its Two Forms

The offset factor may appear in either of two forms, and both are potential neutralizers of the detractive impact of disputes. One of these I call the "current-transfer offset factor" and the other the "time-shift offset factor." The basic characteristic of the current-transfer offset factor in the coal industry is the ability to move orders from mines where coal production has been impaired by a dispute, to mines not so affected. Such movement may be by coal consumers placing orders elsewhere, by operators of multiple units shifting production from one mine to another, by sales agents handling business of many different mines, or indeed, by operators of closed mines purchasing coal elsewhere at such times to fill orders for regular customers.[11]

The time-shift offset factor does not mean any transfer of orders but is simply the power of mines, whether directly affected by a dispute or not, to move production from one operating period to another. This time-shift offset factor itself has two aspects, one of which I call "anticipatory" and the other "retroactive."

The time-shift is anticipatory when the advance prospect of a dispute is clear enough to encourage increased output *before* the stoppage occurs. There is a serious oversight in treating major disputes in the coal industry, and perhaps in other industries also, as if they were comparable to the unannounced spontaneous eruption of a volcano. Rarely is this true. Termination dates of union agreements are public knowledge long before the event, and many major dispute time losses occur under circumstances that facilitate use of the anticipatory feature of the time-shift offset factor.

The retroactive aspect of the time-shift offset appears after the event of the dispute. It provides the possibility of increased output above the levels that would have prevailed for that period had there been no dispute. It functions if there was no anticipatory action or when antici-

[11] Actual cases of this procedure have been found among Indiana mines. Some union mines in Indiana have brought coal from nonunion mines in Kentucky to fill orders during major disputes. Sale through agents is a widespread practice in the industry.

patory action was inadequate to reduce the detractive impact of the dispute to zero.

An essential element of the offset factor, both in its current-transfer and time-shift form, is the presence of unused productive capacity. No offset factor of either type is possible unless output has the potentiality of being expanded significantly and rapidly. But the degree of unused capacity may vary not only through time but also currently from one portion of the industry to another, especially so if productivity is not uniform. Hence, the power of the offset factor to mitigate the impact of a particular dispute depends not only on the time at which the dispute takes place but also upon the geographical location of the part of the industry in which it occurs.

The Current-Transfer Offset Factor

While the element of unused capacity is necessary for both forms of the offset factor, it is not a sufficient condition for creation of the current-transfer. For the current-transfer to be operative it is important that the industry in which a dispute occurs be one composed of a large number of independent firms producing a homogeneous commodity, or at least one where product differentiation is not so pronounced as to seriously limit substitution. It is necessary that some firms be outside the scope of the dispute and also be effective sellers in the same market area served by those firms where the stoppage in production is taking place.

These basic requirements for the current-transfer offset factor are approximated in the bituminous coal industry. Active production of coal takes place in widely scattered mines in thirty different states. While coal is not all of uniform quality, substantial homogeneity is obtained through industrial purchasing on the basis of BTU content rather than by reference to brand names. Most important of all is the fact that these dispersed mines furnish great flexibility in output, and not even the most widely spread dispute has ever encompassed all firms in the industry.

There are, however, two obstacles to prevent the coal industry from fully meeting the basic requirements for a perfect current-transfer offset factor. One of these is noticeable product differentiation for the coking quality coals, combined with nearly complete ownership of these coals by the industrial consumers. Both the large difference in quality and special ownership serve to remove these coals, which represent perhaps 16 to 19 per cent of total output, from the commercial market. The net effect is that the current-transfer offset factor can contribute little to reduce the impact of dispute time losses occurring within these "captive" mines, and neither does it gain any support from

the operation of these mines when the commercial mines are closed down. On the other hand, the power of current-transfer in the commercial branch of the industry cannot be fully allowed for in our measurements. Statistical materials do not permit the monthly production and disputes time records to be split into units dealing with commercial and consumer-owned mines separately. Failure to do so tends to give a distorted impression of the extent of unionism. Thus, it also contributes to a misleading underestimate of the full power of current-transfer in the commercial branch of the industry.

The other important obstacle is concerned with mine location and transportation problems. Even if all coals other than the special coking coals entered in the commercial market and were uniform in character (which they are not), thousands of mines in the many states are not all equally available to consumers everywhere. Thus, the presence of large unused capacity in the bituminous mines of Utah permits no possibility of a current-transfer offset to mitigate the impact on production of a dispute which closes down all the mines in the great industrial consuming centers east of the Mississippi. The cost of shipment of a bulky commodity fixes the limits of the area within which the operation of the current-transfer offset factor can take place. But the determination of the boundaries of the market area by transport costs is not peculiar to the coal industry. What does seem to be special for this industry is that the available transportation facilities tend to be exhausted long before the limits of productive capacity to mine coal are reached. Hence the presence of unused capacity for the coal industry itself may be less important for the operation of the offset factor (in both forms) than the availability of rolling stock in the railroads upon which the industry must rely for delivery of about 80 per cent of its output. For the current-transfer offset factor to operate fully, not only must there be unfilled rail cars at the right time, but they must be available to serve the mines that are not affected by the dispute.

Even if the productivity of all the mines were uniform, location of the area of a dispute might still be important in determining the power of the current-transfer offset. Widening the extent of unionism makes disputes arising over failure to agree upon renewal of contracts spread over a larger area. Hence, it also tends to weaken the force of the offset factor in this form.

The Time-Shift Offset Factor

Number of firms, homogeneity of product, or extent of the dispute area are of much less importance for the operation of the time-shift offset factor. Indeed this form of offset may mitigate the impact of a

dispute which brings about closing of *all* coal mines for a short period. Just as in the case of current-transfer, its power would be limited by the degree of unused capacity in the industry. Here too the decisive element may not be the capacity to mine more coal but the availability of additional transportation facilities.[12] During a localized dispute the time-shift offset factor might operate as a supplement to current-transfer, but its strength does not rest on the location of a particular dispute. What counts most in determining the real power of the time-shift is the *duration* of the dispute. This is because of the fact that the longer the dispute lasts, the less significant becomes a given margin of unused capacity existing before the beginning of the dispute. The power of the anticipatory feature of the time-shift offset is thereby reduced.

However, given a dispute of short duration, the anticipatory feature of the time-shift can go into effect either regionally or on an even broader scale providing there is unused capacity and reason to believe that a stoppage of production may be imminent. The time-shift offset can hardly act concurrently with the current-transfer but it may serve as an important supplement.

At the other end, the supplemental strength of the retroactive feature of the time-shift offset factor is derived from the ability of consumers to wait upon production. At least since 1947 in the American economy generally, this ability probably has been much greater than assumed during the heated controversies associated with major disputes.[13] For

[12] Writing in 1923, Tryon and Wing made this significant statement, which is still valid and important: "If the mines are generally at work, the limiting factor becomes transportation, and further increase in price encourages the opening of thousands of wagon mines which, under the law, can demand transportation and whose activities so dilute the available car supply handled by the carriers." David L. Wing and F. G. Tryon, "Fluctuations in Coal Production," Ch. XV in Persons, et al., *The Problem of Business Forecasting* (Boston, 1923), p. 200.

Ten days prior to a U.M.W. announced closing of mines, the author had an interview with an executive of one of the large coal companies. The interview was interrupted many times while this official negotiated by telephone with industrial buyers for advance orders and with railroad officials for additional freight cars. There was no question about ability to mine the coal and hardly any as to getting advance orders; it was shortage of shipping facilities that appeared as the real capacity limitation. While this official apologized for the interruptions, he might well have charged the author a fee for carrying on an excellent laboratory demonstration of the time-shift offset factor in actual operation.

[13] The retroactive feature of the time-shift offset factor is real for other industries besides coal. Thus, consider the following statement from the *Monthly Letter on Economic Conditions and Government Finance of the National City Bank of New York:* "The year 1952 has closed with most of the overall measures of business at new highs and with spreading confidence in the outlook. *Some observers doubt that the business indexes would now be as high if there had been no steel strike or catching up period afterward,* but *debate* on *that point* would be *idle.* The important matter is that production organization has again surpassed all previous accomplishments. Not only in dollar values, but in physical terms, which are the measures of welfare, the output of goods and services during the year has set another new record" (Jan. 1953 issue), p. 1, (italics mine). While "debate" may be "idle," critical examination of "that point" is not.

the coal industry some measure of this ability is possible through a study of the records of consumer stock piles. Although this matter is reserved for separate study later, it is mentioned here because it leads to observation of the interrelation between the anticipatory and retroactive features of the time-shift offset factor. It is the building up of excess consumer stocks through the anticipatory feature and their relation to consumer use during the dispute that may determine whether the retroactive time-shift offset factor later comes into operation at all.

Interrelations of the Various Forces

The detractive impact of dispute time losses will reduce current output unless it is attenuated by the current-transfer offset factor. It exerts its full force if a dispute covers an entire industry under conditions of constant or increasing demand for the product. During a period of decreasing demand a dispute may have no effect on total output unless the time loss involved is greater than would have occurred as a result of the shrinking demand requirements taken alone. In that case the impact of the dispute becomes detractive to the extent that output reductions result from this excess time loss, and the remaining impact is distributive. We cannot take the detractive and distributive impacts of disputes as if they were forces always appearing separately; in actual situations they may be combined, and it may be difficult to disentangle them for study.

So, too, the different forms of the offset factor may be blended together, in certain cases. A prospective dispute which threatens to close half of the operating coal mines may encourage a great burst in output among all the mines, which later may be augmented still more within the mines that are not shut down. Such blending, however, does not mean that the current-transfer and time-shift are in fact companionate forces. They are, indeed, more emphatically alternative and complementary to each other. The known presence of a strong current-transfer tends to reduce the importance of the time-shift offset factor. Conversely, the absence of current-transfer increases the significance of time-shift. Just so, a too mild reliance upon the anticipatory feature may increase the use of the retroactive feature after a dispute has been settled.

III. *The Application of the Offset Theory to the Empirical Record*

The Correlation Procedure

If there were no offset factor at work, and also if no other forces than dispute time losses contributed to fluctuations in monthly output, then monthly production would be directly correlated with dispute man-day losses and the coefficient of correlation between them should

be -1.0. This is the mathematical form which the layman's view of the impact of disputes on production would take. If, however, no external forces were at work to produce output variations, but there was nevertheless a strong current-transfer offset factor whenever a dispute occurred, the correlation coefficient would approach zero, its actual value being dependent upon the strength of the current-transfer offset. If the current-transfer offset were only powerful enough to neutralize about half the impact of a dispute, but no more, then the coefficient would calculate to $-.7$ ($r^2 = .49$). Unfortunately, all the other external forces cannot even be identified, to say nothing of being extracted from the statistical record. Hence, such coefficients cannot be relied upon to have these precise meanings.

However, if all other external forces could be identified and extracted, our monthly figures still could not show the full force of the time-shift offset factor even if it was known to be present. Only if the time-shift operates within the month when a dispute occurs will it contribute directly to reducing the correlation calculations. A high correlation coefficient between monthly output and dispute man-day losses is indication of weakness of the current-transfer, but it does not mean that the time-shift offset factor is ineffectual. Rather it may mean that in emphasizing the direct relation between production and time-losses in the major dispute months the effectiveness of the time-shift offset factor which must come in the minor dispute months is subordinated.

If the components of the offset factor have been properly identified, given a situation in which all mines are producing at full capacity when a dispute occurs, or is impending, there is no possibility of immediate short-time expansion. If the dispute involves all mines, it follows that the offset factor in both forms has no power. The immediate impact of disputes time losses upon production is then, and I would say *only then,* direct and complete; the correlation coefficients will be close to -1.0. No allowance would need to be made for the fact that monthly calculations may tend to obscure the anticipatory and retroactive features of the offset factor in this case. However, even close approximation to such cases is rare. In the entire eighteen-year period even the disputes of April-May 1946 only faintly resemble such a situation.

In an attempt to apply the theory of the offset factor to empirical data, the figures for all years are classified in seven groups, each containing years with generally similar economic conditions. This breaks the nine-year record of 1933-1941 into three segments. The first of these, labeled Segment A, consists of the three major dispute years of initial economic revival, 1933, 1934, and 1935; a second segment labeled B is made up of the minor dispute years, 1936, 1938, and 1940;

and finally the third Segment C containing the three major dispute years, 1937, 1939, and 1941, represents a secondary revival group. The 1942-1950 period breaks into four segments. The war years, 1942-1945, contain two major dispute years, 1943 and 1945, making Segment D, and two minor dispute years, 1942 and 1944, making Segment E. The other five years of the postwar period break into two clear segments with major dispute years in each of them. The first of these is the postwar reconversion Segment F, 1946, 1947, and 1948, while Segment G might be called the postreconstruction slump consisting of the two years, 1949 and 1950.

Calculations for 1933-1941

For each of these segments scatter diagrams were made of monthly national use production (Y in millions of tons) in relation to dispute man-day losses (X in thousands of man-days). Regression lines were constructed for each of these diagrams and Table I contains the figures showing the results of these calculations for the major dispute years of the nine-year period, 1933-1941. Results of the next step of determining correlation coefficients[14] between national use production and disputes man-day losses for these same segments of this nine-year period are also presented.

These calculations reveal that a regression line for the period 1933, 1934, and 1935 begins at a lower level (28.6 million tons monthly) and falls at a much less rapid rate (1.28 million tons per million man-day losses) than does a similarly constructed line for the three years, 1937, 1939, and 1941. For the latter segment (C) the regression line begins at 38.9 million tons monthly and falls at a rate of 6.86 million tons per million man-day losses. The correlation computations show clearly that prior to 1936, dispute time losses had a negligible effect on total coal production. The correlation between unadjusted monthly production and dispute time losses of —.10 is so low as to be unimpressive, and when trend and seasonal variation in output are allowed for, the correlation —.17 is still negligible. The one could account for barely one per cent ($r^2 = .01$) of monthly fluctuations in output, and the second, with seasonality allowed for, still would not explain three per cent

[14] Tests to determine whether these correlation coefficients are significantly different from zero have been made. The results showed the correlation coefficients were not significant for Segment A, but were significant for the major dispute Segment C. The actual calculations of $\frac{r}{\sigma r}$ were —.5914 in segment A, r based on national use production and —1.005 (if r was calculated on adjusted production figures). The corresponding calculations for the C Segment give —4.672 when applied to the unadjusted correlations and —4.61 for the other series.

TABLE I.—RELATION OF MONTHLY NATIONAL USE PRODUCTION TO DISPUTE MAN-DAY LOSSES, 1933–1941

	Major Dispute Years		Minor Dispute Years
	A 1933, 34, & 35	C 1937, 39, & 41	B 1936, 38, & 40
Regression Line:[a]			
Begins at Level	28.68	38.99	—
Rate of Fall	1.28	6.86	—
Correlation Coefficients:[b]			
Unadjusted	−.10	−.79	−.16
Adjusted	−.17	−.78	+.49

[a] Figures in millions of tons and rate of fall per million man-days.
[b] Monthly national use production, Y, and dispute time losses, X.

($r^2 = .028$). This suggests that the detractive impact was largely spurious, and that which was real was neutralized by the offset factor in current-transfer form.

Construction of a regression line showing rate of fall in production per million man-day losses for Segment B, the minor dispute years, would be a curiosity without much meaning, as no single month involved as much as a 75,000 man-day loss. Nevertheless, the correlation coefficients were calculated to show how slightly such time losses influenced the total production record. Hardly noticeable if correlated with unadjusted production volume (−.16), with allowance for seasonal and trend factors, the positive correlation coefficient suggests that disputes stimulated increases in output. Of course, the positive correlation coefficient of +.49 is misleading and means merely that if seasonal adjustments are made, dispute time losses of the magnitude involved for these three years were easily absorbed. Speaking broadly and freely, such individual strikes or lockouts may determine *what* mines will *not* produce in a particular week but they cannot bring about increases in total output. They are small enough so that especially in periods of a generally wide margin of unused capacity the current-transfer offset factor will neutralize them completely and output will reach levels established by other forces.

The contrast between Segment C and A is striking. Output has now reached higher levels and the duration as well as magnitude of disputes has been increased (see chart). Our regression line which begins at a production level of 38.9 million tons monthly falls at a rate of 6.86 million tons per million man-days dispute time losses.

The correlation coefficient between monthly production and man-day

losses which is $-.79$ when using unadjusted production figures, falls only slightly (to $-.78$), when output data are adjusted for seasonal and trend forces. This means that for these three years, more than 60 per cent of monthly fluctuations in production ($r^2 = 62.4$, or 60.8 if output is adjusted) were associated with dispute time losses.

Thus, the impact of disputes on production volume in the years of Segment C was considerably more than in earlier years. Although still present, the offset factor, especially in its current-transfer form, has lost some of its power. It would be a mistake, however, to think that the power of the offset factor had disappeared. Actually, the time losses of Segment C, although greater than those for A, never absorbed as much as a full month of working time. The largest of these, in April 1941 5.25 million man-days, were roughly two-thirds the monthly working time of the industry.

Other monthly time losses in Segment C were all of less magnitude. The effort to gain general acceptance of the renewed union agreement in April 1937 involved losses of 978,000 man-days during that month, and each of the four succeeding months also showed dispute time losses between 100,000 and 300,000 man-days. The renewal of agreements two years later associated with the effort to establish general acceptance of the union shop brought time losses of 4.23 million man-days in April and 2.75 million in May.

An increase from one to four million monthly dispute time losses, taken alone, will tend to reduce the power of the offset factor, but such an increase still needs to be examined in relation to other factors. At no time during 1937, 1939 and 1941 could it be said that bituminous coal mining operated at full capacity. Only eleven months during the entire three years showed reported weekly working time above 30 hours, and in none of these did hours per week fully reach the U.M.W. standard of 35. The operation of the current-transfer form of the offset factor is shown concretely by the substantial increase in the relative proportion of output from the partially unionized states of Illinois and Western Kentucky during the major dispute months of 1939 and 1941. Moreover, great increases in output in the months before April in both 1939 and 1941 are indicative of the operation of time-shift on a substantial scale.

The Calculations for 1942-1950

The calculations of the relation of monthly production to dispute time losses for 1942-1950 yield a very different result from that for the earlier nine years. The figures for regression lines showing rate of fall in monthly output per million man-days for these years, along with

correlation coefficients between production and dispute time losses, appear in Table II.

TABLE II.—RELATION OF MONTHLY NATIONAL USE PRODUCTION TO DISPUTE MAN-DAY LOSSES, 1942–1950

	Major Dispute Years			Minor Dispute Years
	D 1943 & 45	F 1946, 47, & 48	G 1949 & 50	E 1942 & 44
Regression Line:[a]				
Begins at Level	48.3	48.7	42.3	—
Rate of Fall	4.45	5.03	4.90	—
Correlation Coefficients:[b]				
Unadjusted	−.84	−.90	−.81	+.32
Adjusted	−.81	−.92	−.82	+.39

[a] Figures in millions of tons and rate of fall per million man-days.
[b] Monthly national use production, Y, and dispute time losses, X.

Here the computed regressions for all the major dispute segments would begin at higher levels and fall at less rapid rates than was true for the major dispute Segment C of 1933-1941. When correlation coefficients are computed,[15] the increased force of the detractive impact of disputes upon production becomes very clear. For the two war years, 1943 and 1945, the correlation coefficient between national use production and monthly dispute time losses is −.84. When volume is adjusted seasonally and for trend, the result is a coefficient of −.81. It seems safe to say that over 65 per cent (r^2 = 68.7, or 64.8 if output is adjusted) of the monthly variation in output is explained by dispute time losses. Again the correlations for the minor dispute years 1942 and 1944 (E), like those for Segment B of the earlier period, do not mean what they seem to say. The positive correlations are indicative of the great productive capacity of the industry in these years with few small dispute losses.

[15] Similar tests to those made for correlations of 1933-1941 confirm the increased significance of the relation of production to dispute time losses for the second nine-year period. For the two major dispute years of the war period (D), a t-test gives a result of $t = -7.262$ when applied to the unadjusted production coefficient and −6.47 when the adjusted production calculation is used. The same test for the two year Segment G gives $t = -6.479$ or −6.72 depending upon whether the correlation is calculated on unadjusted or adjusted production respectively. For the postwar reconversion Segment (F), when 36 months permit the $\frac{r}{\sigma r}$ formula the result is −5.32 and −5.44 on unadjusted and adjusted data.

A still more pronounced relation between production variations and dispute time losses appears for the postwar reconversion years, 1946, 1947, and 1948. Here the correlation coefficient rises to a new height of −.90 or −.92 depending upon whether unadjusted or adjusted output figures are used. This, then, indicates that over 80 per cent of the monthly production variation is accounted for by dispute time losses (r^2 = 81, or 84.6 if output is adjusted). It may also be observed that for the first time, adjustment for seasonality and trend raises rather than lowers the correlation coefficient. This is also true for the two post-reconversion slump years, 1949 and 1950. Our correlation coefficient for these years is −.81 when national use production figures are involved and −.82 when they are adjusted seasonally and for trend. In either case, we have again over two-thirds of monthly variations in output (r^2 = 65.6, or 67.2 if output is adjusted) definitely associated with disputes time losses.

The record then shows that the apparent detractive impact of disputes on production has been substantially greater since 1942 than it was in the earlier years. In part, this is attributed to a weakening of the offset factor, especially in its current-transfer form. It was pointed out earlier that essential components of the offset factor were immediate shiftability of orders and unused capacity. In the application of the theory to post-1941 conditions, therefore, it is relevant to re-emphasize the expanded orbit of unionism and the fact that the major disputes concerning renewal of agreements may encompass about 80 per cent of potential industrial output. Moreover, the expansion of aggregate output of the war and postwar years pushed the actual output levels closer to full capacity.[16]

[16] By request of the Hard Fuels Coordinator, the U.M.W. and the Northern Appalachian Coal Operators Association modified the then (Jan., 1943) existing agreement so as to permit a six-day week with overtime payment for work above 35 hours. See *Proceedings Thirty-Eighth Constitutional Convention of U.M.W.A.* (Washington, D.C., 1944), p. 93. Later, ceiling prices on coal were adjusted upward by O.P.A. (p. 104). It was alleged, however, that although prices were actually advanced to the new ceilings, the six-day week with punitive overtime was rarely followed (p. 144). Operator representatives deny this (p. 146). For present purposes I have not attempted to determine the accuracy of these claims. It is enough now to reveal that the record shows a clear margin of unused capacity during all of 1943. Even in the four major dispute months of May, June, October and November, when extra working time may not have been available in some weeks, full use seems not to have been made of all potential working time in other weeks. Reported average hours worked weekly for the two years, 1942 and 1943, were as follows:

Year	Jan.	Feb.	Mar.	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
1942	31.3	31.6	31.5	31.8	32.7	33.2	29.7	32.1	33.5	34.2	34.4	35.7
1943	34.7	37.0	38.6	36.9	<u>35.2</u>	<u>28.4</u>	37.1	40.3	39.4	<u>39.0</u>	<u>28.6</u>	44.6

Major dispute months are underscored.

IV. *Supplemental Examination of 1942-1950 Segments*

The War Years

Since the correlation analysis used thus far is more indicative of changes in the power of the current-transfer form of the offset factor than it is of time-shift, more detailed examination of the individual segments of 1942-1950 is now required. For the war years, 1943 and 1945, disputes were not equal in magnitude to those of 1939 and 1941, although they were greater than those of 1933, 1934, and 1935 (see chart). Since this was so, even an offset factor weaker than in 1939 and 1941 might be sufficient to neutralize the dispute impact. In spite of the fact that higher output volume and expansion of unionism reduced the strength of the current-transfer offset, there are clear indications of its continued vitality. Imperfections of materials prevent a direct observation, but if our vision cannot be clear, neither is it completely obscured.

A glimpse of the forces at work is to be had from the varying character of state production records for 1943, compared with those for 1942, when dispute time losses were of a minor character.

If all coal producing states showed the same rate of increase or decrease in 1943 monthly production compared with the same months of 1942, then the 1942 proportions of total tonnage for each state would not change. On the other hand, a rate of change in one state's tonnage that varies from that of other states indicates a shift in the relative position of that state. Such shifting proportions of state production are too crude to be used as measurements, but they are nevertheless rough indicators of the strength of the offset factor. We know that Virginia, West Virginia, Western Kentucky, and Illinois are at least partially outside the spheres of control of the U.M.W. Hence, if during critical dispute periods, output in these states rises sharply, it suggests that the current-transfer offset factor is operating vigorously. Unfortunately, the state units, except perhaps for Western Kentucky, are all too large to isolate in pure form the areas not covered by major union disputes.

It should be remembered that 1943 was the war year with the prolonged controversy as to portal-to-portal pay. This controversy, while it turned out to be the basis for several interruptions in coal production, was of special importance since it involved the application of the Fair Labor Standards Act to all firms dealing in interstate commerce. Therefore, it could not be strictly insulated either within U.M.W. influence or indeed within the coal industry taken alone.[17]

[17] For details of the scope of the controversy see U. S. Congress, Senate Committee on Judiciary, *Report of the Portal Bill*, S. Rept. No. 37, 80th Cong., 1st Sess. (1947).

The critical months of 1943 were June and November with 3 million and 2.1 million dispute man-day losses respectively; but Apri May and October also were months with over 300,000 man-day losse Examination of the state records reveals that in the major dispu month June 1943, when output for all coal producing states was dow to 71 per cent, Western Kentucky and Illinois produced almost 90 pe cent of their volume for the corresponding month of 1942. Virginia an West Virginia, with smaller numbers of mines outside U.M.W. influ ence, exceeded the national average for all coal producing states onl slightly. The relatively greater volume during this critical month fo Western Kentucky and Illinois is the current-transfer offset factor a work. Moreover, the figures also show the same force at work in the les critical month of November, when smaller time losses contribute t reducing national output to 93.9 per cent, while Illinois and Wester Kentucky more than match the 1942 output level.

More striking than this blurred picture of the current-transfer offse factor is the revelation of the power of the time-shift offset factor i 1943. The U.M.W. 1941 two-year agreement, then in effect, was du to terminate March 31. This was not only common knowledge, bu there was clear warning, as early as February 10, that renewal wa likely to be associated with some dispute since on that date norther and southern operators indicated unwillingness to accept U.M.W Policy Committee proposals. In testifying before the Truman Com mittee on March 26, Mr. Lewis cited the Tennessee Coal and Iro Case to indicate the new importance of the portal-to-portal pay issue.[18]

Under such circumstances the time-shift offset factor came into pla Output in all coal producing states in January 1943 was about com parable with that for 1942, but February and March showed shar increases in volume everywhere. In March 1943 national use pro duction reached the enormous total of 55 million tons, a figure neve reached for any other month in our entire eighteen-year record, excep January 1947.[19] The dramatic appearance of the anticipatory time shift offset factor, therefore, is shown clearly.

Further observation reveals also the appearance of the time-shift in it retroactive form. While the U.M.W. agreement, due to expire Marc 31, was not renewed on time, it was extended for thirty days on Presi dential request, and a second failure to renew resulted in governmen seizure of the mines early in May. April and May, therefore, wer

[18] See *Proceedings Thirty-Eighth Constitutional Convention, U.M.W.* (Washingto D.C., 1944), pp. 93, 95, 97, and 112.

[19] Because of heavy exports in the postwar period, total output exceeded this figure in or month of 1946, four months of 1947 and two months of 1948.

months with no formal disputes, but sporadic walkouts brought 350,000 and 680,000 man-day losses in these months respectively. Time losses of these dimensions were easily neutralized, and 1943 output was about equal to that for 1942 in both months.

Apart from the strength of the offset factor already noticed, both in the current-transfer form and the anticipatory time-shift before June, there were also clear signs of its retroactive form in the months following June. Save for October and November, all the remaining months of the year brought production to levels considerably above those for the preceding year. The remarkable feature of the year 1943 was not that there were five months, each with dispute losses of more than 300,000 man-days; but rather that, in spite of about six per cent shrinkage in production workers, and 7.5 million annual dispute man-day losses compared with about 264,000 in 1942, the total output for the year was 101.4 per cent of that for 1942. It is difficult to read such a record without feeling the power of the offset factor hoisting the coal cars to the tipple!

The other major dispute year of the war, 1945, presents a different pattern; for while the war did not close until late in that year, military industrial production began to fall early in the year. The industrial production index which began at the same level as in 1944, sagged noticeably in April, and continued to do so throughout the rest of the year. It would be expected that such general industrial retrenchment would show itself in reduced coal output, which did prove to be the case.

The coal output shrinkage of 1945 was evident during the entire year until the winter months of November and December, when production rose a little above that for 1944. This falling output meant a widening margin of unused capacity during a year when dispute time losses, although significant, were still not as large as in 1943. The time losses of April and May, 672,000 and 347,000 man-days respectively, were scattered and associated with sporadic outbursts rather than general official stoppages. U.M.W. officials, recommending an extension of work for thirty days after the March 31 agreement termination date, seemed unable to muster enough disciplined support to prevent individual defections.

Such individual defections in a period of sagging demand cannot have even a distributive impact on production. This impact must depend on the breadth of the dispute time loss. For if the margin of unused capacity is becoming wider, and numerous scattered mines are untouched by the defections, these can easily absorb the unfilled orders of the mines that are closed. Hence the current-transfer offset factor effectively prevents a broad distribution of the shrinkage in total pro-

duction requirements and forces concentration on those mines where the sporadic stoppages are occurring. With current-transfer having such power, the time-shift offset factor will hardly operate at all.

Thus April production was well over 40 million tons and was 88 per cent of that for the same month in 1944. But since the operation of the current-transfer offset factor is spread widely under circumstances of such sporadic minor disputes, the results are not strikingly apparent in production records for individual localities. The output in the partially organized centers shows only slightly better positions than in 1944.

The Postwar Reconversion Years—1946, 1947, and 1948

The high correlation between the monthly production record and dispute time losses for these three years calls for some special attention. First, one needs to point out that both in terms of extent and duration the dispute time losses of this segment are of larger magnitude than for any other portion of the eighteen-year period. From this standpoint, no earlier year matched 1946, although the 1948 record was not far below.

The significance of 1946 as the year of transition cannot be overemphasized. While started in 1945, reconversion was far from complete at the close of that year. The prolonged automobile dispute which began in November did not come to an end until March 13, 1946, and heavy industry was not back to full-scale operation until after the first quarter of 1946. This point becomes sharpened with the detail that the April 1946 index of industrial production (1935-1939 = 100) stood at 190 as compared with 336 in April of the preceding year.[20]

It is the magnitude of the 1946 disputes which has the most direct bearing on the operation of the current-transfer offset factor. Reference to the chart shows graphically that April 1946 comes closer to demonstrating the layman's view of the impact of disputes upon production than does any other portion of the eighteen-year record. Dispute time losses of 7.5 million man-days were recorded for April, and national use production fell to 1.6 million tons. In no other month had the bituminous coal industry come so close to a total shutdown. Moreover, curtailment of output seems to have been general, as I find no evidence of any shift in the relative importance of any of the large coal producing states. The current-transfer offset factor, if indeed it was not completely broken down, seems to have been sent to the shop for repair.

However, contrary to the simple view that disputes have a direct

[20] H. M. Douty: "Review of Basic American Labor Conditions," *Labor in Post-War America* (Brooklyn, 1949), p. 110.

impact on production commensurate with the amount of time lost, the current-transfer offset factor seemed to have made a quick recovery. Recorded dispute time lost for the very next month of May was only slightly under (7.2 million man-days) that for April, but national use production came back to a level just under 19 million tons. Moreover, this rapid return to higher level output occurred with another shift in the relative importance of the different coal producing areas; this time it was Ohio, Illinois, and West Virginia that seemed to share the honors of temporarily improved positions.

Reduction in the power of the current-transfer offset by the large-scale dispute losses in the early part of the year, however, was not the only feature of 1946 that deserves emphasis. Long before the April disputes time losses set in, the work of the anticipatory feature of the time-shift offset factor had come into evidence. Even while major disputes in the heavy industries were reducing the amounts of the then current coal requirements, the output of mined coal was rising sharply. National use production for the first three months of 1946 exceeded any other first quarter except for the year 1944; and even 1944 would have been subordinate to 1946 if the comparison were made on the basis of total production with the huge volume of exports included (see chart). Once this is observed, the theory of the offset factor in the form of time-shift becomes a rational explanation.

Even with a strong anticipatory time-shift factor, however, the dispute time losses of 1946 were of such magnitude as to deplete substantial accumulated reserve stocks. Hence the other feature of the time-shift also becomes of significance. If the larger-scale dispute time losses of April-May impaired output substantially and reduced accumulated inventories, nevertheless the retroactive features of the time-shift offset also provided for a speedy revival. Total output for the summer months, June, July and August, exceeded that for any other year in the entire record, including the bumper year of 1944. Even with greatly expanded export shipment, summer month output for national use was still slightly above that for each of the two preceding years.[21]

[21] From the shipper's point of view the story was told dramatically thus: "The brilliance which characterized the monthly shipments of bituminous coal from Lake Erie during such parts of the season 1946 when the railroads and vessels were amply supplied with cargo coal can best be evaluated not through the accomplishments of the preceding season, but by comparison with the trade of 1944 when splendid sailing conditions, precision of dispatch and a larger fleet of vessels conspired to bring about the all-time record movement of approximately 53 million tons. . . . Following the sharp recovery to 6½ million tons in June loadings, there ensued an unprecedented flood of coal from mines to lake front docks, thence by vessels to destination. During 123 days of shipping, July 1 to October 31, all former monthly records were broken, and total shipments of 31,758,621 tons constituted 65.82 per cent of the entire season's soft coal shipments." See *Annual Report of the Lake Carrier's Association* (Cleveland, 1946), p. 68.

The records for 1947 and 1948 follow somewhat the same patterns as that of 1946 in attenuated form. Although both can be classified as major dispute years in accordance with our scale, neither of them came even close to matching the 1946 record. In both years, the major dispute months brought some mild shifting of state positions and were preceded by months of expanding total production. The July (6-14) dispute losses in 1948 require some special mention since these were confined to the "captive" mines. Partly because of their limited scope, but more particularly because of the specialized character of the production, we can find no sign of any area shifting that suggests the operation of the current-transfer offset factor at work.

The Post-Reconstruction Slump—1949-1950

The rising trend of coal production of the nine years, 1933-1941, graphically presented, becomes a series of mountain peaks and intervening valleys formed by the seasonal variations, with dispute time losses seeming to blend in with the seasons. The graphic pattern which suggests the mountain climbing course, leads to the long high plateau, which begins in 1942 and continues until 1949 with regularity not found in the earlier period. Indeed, it is almost correct to say that such irregularity as may be found in the post-1941 period is associated with the dispute time losses along with the anticipatory and retroactive compensation for their impact. But the graphic picture of the plateau changes with 1949, as if nature had cut a giant gorge into the landscape. The steep descent of the first part of 1949, broken by the influence of disputes time losses, comes to an end only late in the year, when the pinnacle of winter production has to be crossed before reaching the new plateau level of 1950 (see chart). This language like all impressionism, suggests but does not describe the actual course of the production record.

The continuing slump through all of 1949, shown by the falling index of industrial production and by the rising volume of unemployment, brought with it recession in coal orders.[22] Under such circumstances only the distributive impact can be real, and the apparent detractive impact is bound to be spurious. Falling total industrial demand is certain to bring with it a decline in coal requirements. Understanding of the 1949 record requires a realization that the forces

[22] During the last half of 1948 there were feeble suggestions that recession might be forthcoming. Even though the industrial production index and the volume of employment seemed to be maintained throughout the year, the average weekly working time in manufacturing during the last half of 1948 was slightly under that prevailing for the first half. See Council of Economic Advisers, *The Annual Economic Review* (Washington, D.C., 1950), pp. 157, 169, and 170.

contributing to the decline in coal requirements *preceded* the major dispute time losses and were not created by them.

The year 1949 was not only special in that it was a year of recession, but also in that there were a number of weeks which involved officially directed union reductions in working time which were not classified as disputes losses. Thus the U.M.W.-ordered three-day week, which began the first week in July and extended through August and half of September, was not counted as a labor dispute in the BLS series of disputes man-day losses, but the walkouts beginning September 19 in protest to the stoppage of Welfare and Retirement Fund payments, are included. Technically, the largest dispute man-day losses of the year were those associated with these walkouts, which continued until after a meeting of the U.M.W. policy committee resulted in ordering "the 305,000 soft coal miners east of the Mississippi back to work until November 30, 1949." Failure to reach a new agreement in November brought another general order of a three-day week effective December 5, 1949, but signing of individual agreements with some mines shortly thereafter partially restored the five-day week basis of operation. Dispute time losses of substantial volume continued throughout January and February 1950, until a new National Bituminous Coal Agreement was generally accepted on March 5.[23] Hence, under the special conditions of 1949-1950, the ordinary dispute time losses associated directly with a failure to renew an operating agreement were supplemented with time losses growing out of officially approved reduced weekly work schedules. These supplementary time losses are important, not only for themselves, but as illustrative of points mentioned earlier in our analysis, *i.e.*, that some dispute time losses represent merely another label for reduced operation which would have occurred for other reasons had there been no dispute. The official union orders of a three-day week are a more concrete manifestation of this without the formal pretense of dispute time loss.

The policy, so far as U.M.W. was concerned, was openly stated. The official *U.M.W. Journal* reported:

> . . . divide the orders, share the work program is now a "must" in the soft coal industry. Since the soft coal industry on its own accord, cannot get together and exhibit the business acumen necessary to protect its employees and the business and population of the mining communities, the duty of performing this public service devolves upon the only stabilizing force the industry has ever known, the U.M.W.A.[24]

Still earlier, in announcing the June 13-30 stoppage which was classified

[23] See U.M.W., *Welfare and Retirement Fund: Four Year Summary and Chronology* (Washington, D.C., 1951), pp. 31-43, hereafter cited: *W. & R. Summary*.

[24] *W. & R. Summary*, p. 33.

as a dispute time loss by BLS, President Lewis of the U.M.W. called it:

> . . . a brief stabilizing period of inaction during which cessation of all mining will occur [and stated the reason for this move was that], magnificent production efforts so far this year have resulted in overproduction with consequent economic instability among miners. This period of inaction will emphasize a lack of general stability in the industry and the dangers which will accrue therefrom if current harmful practices are not remedied. It will contribute constructively to the abatement of current economic demoralization; it will not adversely affect the public interest; it will help preserve property values in the industry; and it will help preserve the living standards of the mine workers, their dependents and the communities which depend upon mine workers' incomes.[25]

The view expressed by Mr. Lewis, if correct, may also be extended to other disputes time losses if equivalent working time reduction would take place in any case. It is not a view of the time losses of 1949 that was uniformly accepted. Thus in a National Association of Manufacturers' monograph the disputes time losses of 1949-1950 are regarded as having brought both workers and coal operators immediate serious losses and also as having created later secondary effects on other industries. Unfortunately for this argument, it becomes a little difficult to accept after the admission is made that "Had it not been for the large accumulation of stocks of coal just prior to the beginning of the three-day work week, the coal stoppages of 1949-50 would have brought about an economic crisis."[26]

This admission, if our analysis has been correct, points to the crux of the problem for 1949-1950. The introduction of the three-day week, if extended universally throughout the industry, might have dispersed the force of shrinking demand but could hardly have created a detractive impact on total output. Even in such partially organized pockets as Western Kentucky, the production for all months of 1949 tended to be distinctly under that for 1948, both in months when other areas were little affected by disputes, as well as when the three-day week was in force and large-scale disputes time losses were being sustained. In such a year the current-transfer may exercise only a mild influence in neutralizing the distributive impact of disputes, and the time-shift offset factor is hardly operative at all. If the detractive impact is

[25] *Ibid.*, p. 32.

[26] John G. Gebhart, *The Economic Impact of an Industry Wide Strike: A Case Study of the 1949-50 Coal Strike,* Econ. Policy Div. Ser. No. 27 (New York, National Association of Manufacturers, 1950), p. 10. Bernstein and Lovell in a recent article also seem, in this author's opinion, to misinterpret the 1949 disputes record. See Irving Bernstein and Hugh Lovell, "Are Coal Strikes National Emergencies?" Ind. Lab. Rel. Rev., Apr. 1953, VI, 352-67. Since their article appeared after the present study had been completed, it cannot here be given extended consideration.

spurious, total production tends to take a level which would have prevailed even in the absence of the dispute.

The Concealed Growth of the Strength of the Offset Factor

One additional source of increasing strength in the offset factor must be brought forth into full view. The rate of fall in our regression lines was considerably less for the major dispute year segments of the 1942-1950 period than for Segment C of the earlier nine years. This matter, neglected until other aspects were developed, must now be explained. The real meaning of these differences in the rates of fall per million man-days is that in spite of the larger magnitude of disputes of 1942-1950, their detractive impact was considerably weaker than that of disputes in the earlier nine years. The most important reason for this is to be found in the enhanced power of the offset factor derived from the increased productivity per man-day. Some allowance has already been made for productivity changes. The segments used in calculation of our correlation coefficients were not only designed to group major dispute years into roughly comparable business cycle units, but also to get substantial uniformity in the productivity rates for each segment.[27] However, no effort was made to adjust man-day losses directly for variations in output per man-day.

Compression requires many omissions, but the record has been examined carefully state by state and year by year. Summarized, it shows that increased productivity per man-day since 1941 has been a product of two main forces: great expansion in use of mechanical loading equipment, and an enormous increase in surface mining. In 1935, only 13 per cent of underground production was mechanically loaded, but by 1941 this figure had risen to 41 per cent. Advances during the 1940's were at a slower rate, but by 1950, 68 per cent of deep mined coal was being loaded by machine.[28]

[27] As computed by the Coal Economic Branch of the Bureau of Mines the annual average tonnage productivity per man-day for each year of our segments was as follows:

A	1933	4.78	B	1936	4.62	C	1937	4.69
	1934	4.40		1938	4.89		1939	5.25
	1935	4.50		1940	5.19		1941	5.20

D	1943	5.38	E	1942	5.12	F	1946	6.30	G	1949	6.44
	1945	5.78		1944	5.67		1947	6.42		1950	6.77
							1948	6.26			

[28] Charles James in a careful study concentrating principally on two Pennsylvania counties summarized the development thus: "Mechanical loading, which was of negligible importance before 1930, had risen in importance until, in 1948, roughly seven tons in ten produced underground were loaded wholly or partly by machine.

"The reduction in man-day requirements per ton, which was brought about chiefly by the growth of mechanical loading, permitted operators to keep wage-cost per ton from increasing as sharply as it might have done if wage rates had risen and man-day requirements had not been reduced." *Measuring Productivity in Coal Mining*, Research Rept. No. 13, Industrial Research Dept., University of Pennsylvania (Philadelphia, 1952), p. 68.

Important as has been this increased efficiency underground the still more significant technological change, for this study, is the increase in the proportion of strip-mined coal, from approximately 10 per cent of total tonnage in 1940, to almost 25 per cent in 1950. It is this shift which is the most significant single element accounting for the increase in average annual productivity per man-day. For in a general way it may be said that production per man-day by the strip mining process is from two to four times as great as in underground mining if outputs from underground and strip mines are compared in the same states where both mining methods are in use.

It is not only the proportionate increase in strip mining that we need to examine but the location of that increase. Although coal reserves are widely scattered, about 90 per cent of the total output comes from nine states east of the Mississippi. Among these are Illinois and Indiana, where strip mining got an early start. These two states were responsible for about 60 per cent of the total strip-mined tonnage in 1933 and have continued to place increasing reliance on this method of coal mining ever since. But while both have increased their own percentages of total state production from strip mines, the technological transformation in which they once had the lead has been copied in other states. The transformation began slowly, for as late as 1941 Illinois and Indiana still accounted for about 50 per cent of the strip tonnage. But the force of this technological transformation like a great stream pushing from what seemed to be the headwaters in Illinois and Indiana wound its way into Ohio and Pennsylvania during the 'thirties and then in the next decade meandered on into broader territory to include Kentucky and West Virginia. Thus, in 1950, these six states shared approximately 85 per cent of the national strip tonnage in the following proportions: Illinois and Indiana, 23 per cent; Ohio and Pennsylvania, 40 per cent; Kentucky and West Virginia, about 22 per cent. A review of the shifting of state positions during major dispute periods shows that it was Illinois, Western Kentucky, Ohio, and West Virginia that most frequently showed signs of temporarily improved positions. The fact that these too are areas in which there has been great new growth of strip mining since 1942, and that they are widely separated, has contributed to the strength of the current-transfer offset factor. For the high productivity of strip mining in these areas has increased their ability to neutralize the detractive impact of dispute time losses elsewhere, and their dispersed locations have made their output available to widely scattered consumers. This is one reason why the narrowing of the margin of unused capacity and the broadening of the orbit of unionism that occurred before 1942, did not have their full effect in weakening the power of the current-transfer offset factor.

This regeneration of the current-transfer offset factor occurred because a substantial portion of the new high productivity strip mining of the 1940's was outside the area of the major disputes of that period. To avoid oversimplification it is necessary to observe that it is not true that all strip mining operations have been insulated from the major dispute time losses of 1942-1950. Agreements of the U.M.W. have extended to all strip and underground mines of Indiana, as well as to strip and underground mines responsible for about 75 per cent of Illinois production, and disputes associated with renewals have interrupted mining in these states. But some of the Illinois mines under agreements with P.M.W. are strip mines. Moreover, many of the strip mines of Ohio, Kentucky, and West Virginia have been completely insulated from disputes concerning renewal of national U.M.W. agreements.[29]

But the great contribution which the increased productivity of strip mining has made is to the potency of the time-shift form of the offset factor. Here it has substantial influence throughout both unionized and unorganized areas. It is true, of course, that to the extent this increased productivity has appeared in areas directly affected by large disputes, it has meant that a given number of man-day losses may immediately produce a larger potential shrinkage in tonnage than would have been the case if labor productivity had remained constant. Also, however, this increased productivity has augmented greatly both the anticipatory and retroactive features of the time-shift offset factor. Because of this, even with a somewhat smaller labor force, the coal mines were able to speedily increase production before major dispute time losses were upon them, and return afterwards to higher levels of output more rapidly,[30] in the nine years of 1942-1950 than in the earlier period reviewed. This is the real reason why the calculated rates of fall

[29] Direct communication with the United Mine Workers on the significance of our state calculations resulted in the following statements: "We would concede that your observations, which indicate a significant shift in relative tonnage production of different states during periods of wage disputes, are essentially correct. It is quite true that production is increased in non-union mines during work stoppages. . . . In Ohio and Western Kentucky, there are some unorganized strip mines at the present time, but they do not produce any appreciable tonnage except during cessation of work by the United Mine Workers of America." Letter to the writer from U.M.W. official, dated March 28, 1952.

[30] For special confirmation of this point the author is indebted to Professor Harline of the University of Utah, who writes: "I think that your point that the growth of strip mining has aided the time-shift offset factor is a good one. . . . The simple fact that (underground mines) have to clear the blasted coal away *before* they can get in to make another cut . . . means that it is difficult to speed up the process or store coal underground. . . . In contrast the strip operator can uncover coal for blocks ahead and just let the coal sit there. His ability to do this is limited by the fact that over time the high walls tend to cave. . . . Nevertheless the environment is such that strip mining is still in a better position than underground." Letter dated February 5, 1953.

per million man-day losses after 1952 were distinctly lower than shown by the figures for Segment C of 1933-1941.

V. *The Theory of the Offset Factor in Perspective and The Total Coal Production-Disputes Pattern of 1933-1950*

The theory of the offset factor furnishes us with a clearer understanding of the impact of disputes time losses upon production than has been hitherto available. It gives precise indication of some important elements that must be examined in order to determine the full force of that impact, and so may furnish guidance for policy decisions. By first separating time losses occurring during periods of shrinking demand from those taking place when consumer demand requirements are either maintained or are expanding, the theory makes possible differentiation of the mere distributive impact of time losses from that which is really detractive.

Once the potentiality of a detractive impact has been identified, the different forms of the offset factor may then be examined. This leads to a recognition of the specific conditions that determine the current-transfer and those which make the offset factor take the form of time-shift. While the element of unused capacity is essential for the offset factor in both its forms, the power of current-transfer depends also upon the geographical area to which the dispute time loss may be confined and the degree of product substitution among the individual firms that make up the industry. But though unused capacity is equally essential, it is the duration of disputes that is of greatest supplemental importance in determining the power of the time-shift offset factor. If current-transfer is powerful enough to neutralize the impact of dispute time losses completely, the time-shift form of the offset factor becomes unimportant.

The applicability of the theory of the offset factor to any particular industry depends upon the extent to which these conditions are realized. The bituminous coal industry furnishes a case of close approximation to these essential conditions. Although the theory of the offset factor probably has much broader usefulness than merely to aid in measuring the impact of dispute time losses upon coal production, the possibility of wider application has still to be determined. However, even though the applicability of the theory should prove to be limited to the coal industry alone, its importance would still be substantial; for dispute time losses there easily constitute more than a quarter of the working time lost through labor disputes in American industry as a whole. Even in terms of its applicability to the coal industry, the theory of the offset factor at present merely opens a "little window" on the ground floor, poorly located and too small to furnish a complete view. Beyond our

present horizon lie the answers to important questions of the relation of dispute time losses to miners' wage incomes, to technological changes and employment, to prices for coal, and to coal consumption levels. It will require a larger second-story window to bring these into view.

However, looking at the eighteen-year production-dispute record of the bituminous coal industry from the vantage point of our ground-floor window we have observed a systematic pattern. There was clear evidence that prior to 1937 the impact of dispute time losses on production was easily neutralized by the offset factor in the form of current-transfer, and minor disputes of these years had no noticeable effect. For the later Segment C of our first nine-year period the power of current-transfer was reduced; but nevertheless, in combination with time-shift, it was strong enough to facilitate the continuous upward expansion in coal production.

The reduced power of the offset factor in its current-transfer form manifested itself in the much higher correlation coefficients between production and disputes time losses in the years following 1941. However, the reduction in the power of current-transfer was not as great as these figures suggest. The impossibility of separating the production-dispute record of the "captive" mines from that for the commercial mines tended to magnify the apparent extent of unionism. Hence, the area outside the scope of disputes in the commercial branch of the industry has always been a little larger than appears at first sight. Also great increases in productivity from strip mining, a part of which took place outside the area of major disputes, enhanced the power of current-transfer above that suggested by the calculated figures.

At least some of the large dispute time losses of the 1942-1950 period had no potentially detractive impact upon current coal production at all. This was somewhat true for the time losses of 1945 and certainly for those of 1949. Even the distributive impact of disputes of these years was probably greatly diluted by the regenerated strength which current-transfer derived from the growth of strip mining outside the area of disputes.

It was, however, the great power of the offset factor in its time-shift form which made possible the substantial mitigation of the detractive impact of disputes upon production during 1942-1950. This power grew stronger as current-transfer became more restricted. The potency of time-shift derived largely from the enormous capacity of the coal industry itself was further augmented by increased productivity, partly associated with improved technology underground, but more especially with the rapid development of strip mining. The net effect of the operation of the offset factor in both its forms was to make it possible for U.S. coal production to reach levels considerably above

those for earlier years, even while the amount of dispute time losses also was passing above the highest recorded magnitudes. So great was the output volume that it is extremely doubtful whether, taking the period as a whole, it would have been enhanced at all had there been no dispute time losses whatever. Certainly the claim that dispute time losses in the coal industry produce some kind of an equivalent fall in output simply is not true.

But the impact of disputes on coal production probably is not to be considered analogous to "a widow's cruse in a danaid jar." Rather the great productive capacity of the industry, even when confronted with large dispute time losses, makes it resemble the character of Ovid's miraculous pitcher which Philemon and Baucis found "retained its marvelous quality of being never empty when it was desirable to have it full."

THE BURDEN OF SOVIET TAXATION

By F. D. Holzman*

The principal task faced by Soviet tax authorities is absorption of excess consumer (household) purchasing power generated by the very high rate of non consumption[1] expenditures normally undertaken by the state. The position of the household is particularly central in the Soviet economy because it comprises, with minor exceptions, the entirety of the private sector; since private industry has been virtually nonexistent in the U.S.S.R. for many years, the burden of the state's economic activities must be borne primarily by the household. In this paper an index is presented of changes in the magnitude of this "burden" from 1925/26 until 1950, excluding the war years. Two time series are constructed: (1) consumer money income and (2) taxation (in money) of the consumer; the ratio of (2) to (1) is the average rate of taxation.[2]

The average rate of taxation is one measure of the "burden" of money taxation; this is the definition used by Shirras and Rostas in their study of British taxation.[3] This is the simplest quantitative formulation of the "burden" and is deficient in several respects. First, the extent of the "burden" depends in part on the nature of the public expenditures the taxes are designed to finance. Taxes to finance programs of social security, education, and garbage collection may constitute less of a burden than those used to finance defense, foreign assistance, or long-term investment programs, since the benefits received

* The author, assistant professor of economics at the University of Washington, made this study during the tenure of a fellowship at the Russian Research Center, Harvard University; the assistance of that organization is gratefully acknowledged. He is also indebted to Professor Alexander Gerschenkron, Raymond P. Powell, and Dr. Gregory Grossman for many helpful comments. This paper is part of a larger study of the Soviet tax system which is to be published by the Harvard University Press in 1954.

[1] Nonconsumption is defined here to include all economic activities from which the household receives money income (including transfer payments) but which do not result in output of goods or services for which the household can spend its income. It includes, for example, expenditures on investment in fixed and working capital, military expenditures, state expenditures on health and education, etc.

[2] It should be noted that we include neither income in kind nor taxation in kind explicitly in our series because these cannot be estimated for the period in question with any degree of success (*cf.* fn. 24).

[3] G. F. Shirras and L. Rostas, *The Burden of British Taxation* (New York, 1943), p. 1.

from the former are more immediately perceivable by the taxpayer and to a greater extent may substitute for his own expenditure. Secondly, the psychological impact of a tax depends to a large extent on the form in which the tax is levied; a commodity tax is probably less burdensome than an income tax;[4] and a loan, even though it may never be repaid, may be less burdensome than either of the other two because of the expectation that it may be repaid. Thirdly, the psychological impact of the burden of taxation as we have defined it would depend not only on the average rate of money taxation, but also on the marginal rates and on the absolute levels of income and taxation in *real* terms. That is to say, a nation with a high per capita real income would probably find it less burdensome to pay 20 per cent of its income in the form of taxes than a nation with a low per capita real income. These are but a few of the many factors, economic and institutional, which would cause a divergence between the true psychological burden of taxation and the monetary burden which we will attempt to estimate.

I. *General Methodological Approach*

Measurement of Consumer Money Income

Two independent methods of measuring consumer money income are available to the research worker. The first, and most direct approach, is to add up all sources of income paid out to households over the course of a year. The second approach is to total up household expenditures including changes in savings. Theoretically these two methods should give identical results and a choice made between them should be on grounds of statistical convenience.[5]

Consumer money income will be estimated here from household expenditures. In general it appears more feasible to use this approach, in preference to the income approach, for an extended series of estimates[6] although for certain specific years this may not be the case. The princi-

[4] *Cf.* F. D. Holzman "Commodity and Income Taxation in the Soviet Union," *Jour. Pol. Econ.*, Oct. 1950, LVIII, 425-33.

[5] American economists who have worked on Soviet national income have used both of these approaches. Baran built up his estimates for 1940 for the household from the income side (Paul Baran, "National Income and Product of the U.S.S.R. in 1940," *Rev. Econ. Stat.*, Nov. 1947, XXIX, no. 4); Bergson worked basically from the outlay side in making his estimates for 1937 (Abram Bergson, "Soviet National Income and Product in 1937," (*Quart. Jour. Econ.*, May and August 1950, LXIV, nos. 2, 3); N. Margolin, a Soviet economist, constructs hypothetical estimates of both income and expenditure and discusses, extensively, the methodological problems (N. S. Margolin, *Voprosy balansa denezhnykh dokhodov i raskhody naseleniia* [Problems of the Balance of Receipts and Expenditures of the Population] Moscow, 1940). Although Margolin's estimates are not designated as representing any particular year, they are quite close to figures for 1935.

[6] Gregory Grossman first suggested to me the feasibility of the expenditure approach.

pal stumbling block to the income approach is ambiguity in Soviet data on the total payroll or wagebill of workers and salaried employees.[7] Since the payroll is the largest single receipts item and constitutes about two-thirds of consumer money income, serious doubts would immediately be cast on any income time series based on payroll statistics which did not first explain the observed ambiguities in its magnitude. Retail trade turnover, on the other hand, the largest single expenditure item, is unambiguously available for every prewar year with the exception of 1931. With regard to other receipts and expenditure categories, the difficulties seem to be about equally distributed; the advantage therefore remains with the expenditure approach.

Consumer expenditure categories are considered in greater detail below. The general problems in measuring taxation of the consumer will now be considered.

Defining Taxation of the Household

The approach used in constructing our *principal* series of money taxes on the consumer (Series I to III below) is unorthodox in terms of conventional notions of taxation in capitalist countries; supplementary series (IV to VI) based on more conventional definitions are presented later (Section V).

The unorthodoxy of the present definition stems from the following assumptions:

1. The incidence of all indirect taxes included in the price of all consumers' goods is on the household. This applies to the turnover tax (a sales tax) and to the social insurance markup (a payroll tax).
2. Not only the profits tax paid by state enterprises, but the retained profits of these organizations as well, are considered to be taxes on the consumer. Income taxes paid by the collective farms and other cooperatives are treated similarly.
3. The purchase of government bonds by the population is considered to be a form of taxation.

The first two assumptions are based on the fact, mentioned above, that in the U.S.S.R. there are only two economic sectors, the state and the household; a private industrial (agricultural) sector of consequence no longer exists. Therefore, all taxes included in the price of consumers' goods sold are necessarily paid by the consumer and cannot be shifted backward.[8] Retained profits of state enterprises are no differ-

[7] For discussion of this problem see: A. Bergson, "A Problem in Soviet Statistics," *Rev. Econ. Stat.*, Nov. 1947, XXIX, 234-42; and M. Dobb and H. Schwartz, "Further Appraisals of Russian Economic Statistics," *ibid.*, Feb. 1948, XXX, 34-42.

[8] This is true in an *ex post* sense: all taxes actually paid to the state are paid by the household since there is no other sector to pay them, *i.e.*, the taxes cannot be shifted

ent from profits taxes from the point of view of the consumer: both are markups over explicit costs of production; both constitute financial counterparts to state investment. These two assumptions amount to including in the category, taxes on the household, the total receipts of state enterprises minus their explicit commercial costs. Explicit commercial costs of Soviet enterprises typically consist of payments for labor, raw materials and intermediate products, depreciation, and interest on short-term loans. The following real costs of production are excluded: the return to capital (since the bulk of Soviet investment is financed by interest-free grants from the budget), rent,[9] depletion costs, and depreciation which is typically understated as an explicit cost.[10]

Taxes, as we have defined them implicitly include, therefore, the above elements of factor cost. Our definition of indirect tax would be conceptually much more satisfactory if it were possible to deduct the above-mentioned *implicit* costs from the Soviet markup over commercial cost thereby separating more accurately the factor cost and tax elements in price. This would be difficult to do with any degree of authority since no method has been devised for approximating the value of any of these charges. Baran has assumed that the retained profits of state enterprise represent return to capital;[11] Bergson has assumed that the turnover tax is the only commodity tax and that the remaining markup represents the above-mentioned implicit costs of production.[12] These methods are rejected here because the various elements constituting the markup are arbitrary in size and, in some cases (*e.g.*, retained profits and profits tax) tend to vary in a nonsystematic manner from year to year.[13] The method adopted here provides more consistent results over time. Furthermore, there is not much evidence to indicate that retained profits and other unorthodox tax categories bear a functional relationship to the real economic categories they have been taken to represent. Finally, while the costs of capital, deprecia-

---

backward to private individual recipients of profits income. *Ex ante*, the state may attempt to levy higher taxes on commodities than the household is willing to pay in which case the amount of taxes collected will be less than plan; in effect, the consumer will have shifted the taxes backward to the state. However since we deal with *actual* tax collections, the *ex post* concept is the relevant one for our purposes.

[9] *Cf.* Holzman, *op. cit.*, pp. 430-31.

[10] Bergson, "Soviet National Income and Product," p. 415. Understatement is due to calculating depreciation in terms of original cost with no upward adjustment for the effect of inflation on replacement cost; and to the fact that the Soviets typically overestimate the life of their fixed assets.

[11] Baran, *op. cit.*, p. 230.

[12] Bergson, "Soviet National Income and Product," p. 434.

[13] *Cf.* Table II for profits figures.

tion (part), depletion, and rent may constitute a moderate share of the total of factor costs in the consumers' goods industries, they can be no more than a very small fraction of the total of indirect taxes[14] and even a smaller part of total taxes, and do not substantially affect our estimates.

Our assumption that the purchase of government bonds by the public is a tax is based on the following characteristics attending Soviet bond sales. First, purchases are at best, quasi-compulsory; very strong pressures are brought to bear on the population to invest from two to four weeks income per year in government bonds, an abnormally large amount in view of the low standard of living of the population. Second, by the so-called conversions of 1930, 1936, 1938, and December 14, 1947, the Soviet authorities arbitrarily lowered interest rates, extended maturity dates, and reduced the principal value of outstanding Soviet bonds (by ⅔) so that the public has, until now, recovered only a very small fraction of its investment—and this amount has been seriously depreciated by greatly increased commodity price levels. Economically, sales of Soviet bonds fall somewhere between being a form of taxation and a truly voluntary sale of bonds; in my opinion they have been, until now, more accurately classified as taxes.[15]

These assumptions underlie the first three estimates of the burden of taxation. The estimates may therefore be considered somewhat on the high side. For those who prefer less stringent assumptions, a second trio of estimates have been prepared utilizing more conventional notions of taxation (Section V).

Measurement of Taxation of Household

Although on the surface it appears quite simple to construct a time series of taxes on the consumer because Soviet budgetary data have been relatively accessible, the data are quite imperfect for our purposes.

The first problem arises because the cost of the consumer bill of goods is distorted by subsidies to cover losses in the production of consumers' goods (as well as in the production of producers' goods and raw materials which are subsequently used to produce consumers'

[14] Hodgman says: "Although it is theoretically desirable to include entrepreneurial-type profits, rent, interest, and the wage elements included in 'other money outlays' in value-added by a given industry, . . . the omission of these . . . elements . . . is judged to have no significant effect . . . since (they) . . . are small relative to salaries and wages and payroll taxes." (Donald R. Hodgman, "A New Production Index for Soviet Industry," Rev. Econ. Stat., Nov. 1950, XXXII, 335).

[15] This position is defended at greater length in my forthcoming book. *Cf.* also: Carl Shoup, "Forced Loans," *Curbing Inflation through Taxation* (New York, 1944), pp. 127 ff. Professor Shoup discusses ways of separating out the tax element in forced loans.

goods). The major case in point is the machine tractor station complex (MTS).

The receipts of the MTS valued at the low obligatory delivery prices have typically amounted to less than 25 per cent of their expenditures thereby involving a monetary subsidy from the state. In addition, part of the regular operating subsidies paid to enterprises by the state lower the cost of consumers' goods either directly or indirectly. It may be contended that it is incorrect to designate as a levy on the consumer a tax which finances a subsidy on consumers' goods,[16] since the tax simply substitutes for the true cost of the commodity. If this argument were accepted, consumers' goods subsidies would have to be subtracted from taxes collected from the consumer.

On the other hand, it may be contended that to the extent that consumers' goods are subsidized they take on the character of government services—become part of the nonconsumption expenditures of the state as we have defined them—and must be treated in the same manner. In this case, the subsidies would constitute a legitimate part of the tax burden as we have defined it. There would seem to be two significant differences, however, between services typically underwritten by the state and the subsidies under discussion.

First, the consumers' goods products which benefit from subsidies are commodities which are generally purchased at market price by consumers and are rarely offered to the population free of charge, whereas it is not uncommon for some social services to be distributed free of charge. Second, the subsidies on consumers' commodities are not the result of Soviet social policy but are rather a by-product of (1) the peculiar accounting relationship between the state and the MTS and, (2) an economic policy designed to achieve cost-price stability. For these reasons subsidies on consumers' goods will not be considered part of the tax burden.[17]

No adjustment is required for subsidies to producers' goods industries. The total cost of producers' goods should be included in the value of nonconsumption. To the extent that subsidies to producers' goods industries undervalue such output, the cost of nonconsumption is undervalued. Since the sum of the subsidized cost of producers' goods plus the subsidies is equal to the full cost of output, the tax on the

[16] For example, suppose that a loaf of bread originally sold by the state for two rubles received a one ruble subsidy which was paid for by the consumer in the form of a turnover tax. The consumer would still be paying two rubles for the bread but one ruble would be in the form of a tax and one ruble would be the subsidized cost.

[17] One further argument should be noted. It could be claimed that the MTS are not, in fact, subsidized, but that the monetary subsidy is simply a result of undervaluing, by the use of obligatory delivery prices, the receipts in kind of the MTS. Unfortunately, we do not know the precise extent of the undervaluation. The reader persuaded by this argument can ignore the subsidy adjustment attempted below.

consumer should include payments required to finance both of these categories of state expenditure.

In the statistical study presented below, no adjustment for subsidies to consumers' goods industries has been made in the principal series presented (Series I and II) because the data are not available. For a limited number of years an attempt is made, however, to show the effect on the tax burden of adjusting for such subsidies (Series III).

The second major imperfection in our data exists because a small percentage of the major indirect taxes which appear in the Soviet budget do not fall on the consumer but are levied on producers' goods and to some extent on consumers' goods which are not purchased by the population.[17a] These can in no sense be considered a burden on the consumer but constitute simply a bookkeeping transaction within the state sector. It is impossible to separate out precisely these two categories of indirect taxes. Nevertheless there is enough information to make some reasonable estimates after 1931, and this is done.

A further problem is created by the Soviet practice of collecting the turnover tax largely at the wholesale level, *i.e.*, before the commodities are bought by the household. If, for example, inventories on which the turnover tax is paid, are increasing (decreasing), the rate of tax on the household would be overstated (understated). No attempt is made here to correct for the lag between receipt of tax by the budget and payment by the population.

II. *Some Specific Problems and Assumptions in Measuring Income and Taxation*

In addition to the general methodological problems discussed above, many specific problems arose in constructing the estimates presented below, some due to absence of data and others to imperfections in the data. These will now be considered. Details of the computations and sources of data are presented in an appendix to the paper.[18]

Consumer Outlay Categories

A. Retail trade turnover: Retail trade turnover is the largest category of consumer outlay. It includes all commodities valued at market price which are sold by state and cooperative retail stores and on the collective farm market. Data are available for the whole prewar period under consideration (1925/6-1940). No data are available, however, for 1948-50. The estimates for these years were complicated and are presented in the appendix.

[17a] For example, the profits and turnover taxes on commodities purchased by the Ministry of Armed Forces.

[18] Available upon request from the Russian Research Center, Harvard University, Cambridge, Massachusetts.

The data have to be adjusted for the fact that not all of retail trade sales are to consumers. Bergson (quoting Margolin) points out that 11.5 per cent of state and cooperative store turnover and 10 per cent of collective farm market turnover constitute sales to institutions rather than to the household.[19] The official figures for retail trade turnover are therefore reduced by 11 per cent for all years under consideration. This assumption seems to be in accord with independent data published for the period 1925-30; it is not known whether the percentage of institutional trade in the retail trade turnover has changed in the postwar period.

B. Consumer services: Consumers make substantial outlays for services such as rent, utilities, passenger transportation, amusements, etc. Bergson (*ibid.*), quoting Margolin, indicates that in 1934 and 1938, consumer outlays for services amounted to slightly more than 12 per cent of their outlays for goods. Independent data for 1925-30 give the same percentage. This percentage is assumed valid for the postwar period also, although there is no evidence to either support or refute the assumption.

C. Purchases of government bonds: For most years it was possible to obtain directly figures for sales of bonds to the public. For some years, however, only the total increase in the national debt was available. This includes, in addition, investment of the free reserves of the savings banks, surplus funds of the state insurance organization (*Gosstrakh*), and other minor investors. Since the percentage shares of these different investors in new issues has been fairly constant over time, the purchases by the population can be estimated, without large error, for those years in which only the total loan figures are available.

D. Trade union and other dues: Bergson[20] estimates that expenditures by the population on dues in 1935 were 1 per cent of the total wage bill. Since wage bill data are available for the prewar period, the 1 per cent relationship is used to estimate a figure for dues for each year from 1925 to 1940. Wage bill figures are not available for the postwar period. Social insurance collections, which are a function of the wage bill, are available for all years, however, and are used to estimate trade union and other dues for 1948-50. In 1940, trade union and other dues were 18.8 per cent of the social insurance collection; this ratio is applied to 1948-50. The correctness of the estimate depends on the assumptions (1) that the ratio of trade union and other dues continued to be 1 per cent of the wage bill in the postwar period and (2) that social insurance receipts were a constant percentage of the

[19] Bergson, "Soviet National Income and Product," Appendix, p. 9.
[20] *Ibid.*, p. 10.

wage bill from 1940-50. Both of these assumptions appear to be reasonable; in any case the item is so small that even a large error would have virtually no effect on the results.

E. Purchase of shares in cooperatives: Data for this item are not available after 1930. Since it is small, extrapolation was not attempted and figures are omitted after 1930.

F. Taxes: Direct taxes on the population are a form of consumer outlay and must be included in our total consumer expenditure figure. Indirect taxes paid by the population are included implicitly as part of the retail trade turnover.

G. Deposits in savings banks: The household deposits a small part of its net income each year in savings banks. The increase in savings bank deposits over the year represents another form of income disposal by the household. Data on savings deposits are available for the entire period under consideration.

H. Cash holdings: If consumer outlay is not equal to consumer income, the difference is reflected in a change in the amount of cash held by the household. Therefore in order to estimate consumer income from the outlay side, it is necessary to add the change in cash balances held by the population to consumer outlay. This is equivalent to looking upon the change in cash balances as another way of disposing of income.

Consumer money income is assumed to have been increased (decreased) each year by the increment (decrement) to currency in circulation. The assumption is made that the entire increment to currency in circulation is held by the population.[21] Changes in the amount of currency in circulation are available for all years through 1937, and for 1940. For these years changes in currency in circulation are observed to have been correlated with changes in the average wage rate, the national wage bill (payroll), and the value of retail trade turnover. Using these relationships, estimates were made for 1937-1939 as well as for 1948-1950 (where our estimates of the value of retail trade turnover alone served as a rough guide).

Taxation of the Consumer

Estimates of consumer taxation are fairly straightforward with the exception of the two adjustments mentioned above, *viz.*, (a) to allow for indirect taxes which do not fall on the consumer and (b) to deduct subsidies on consumers' goods from total taxes on the consumer. The

[21] This is a reasonable assumption. Enterprises and organizations hold virtually no cash in their tills with the exception of paydays when the local branch of the state bank supplies enough cash to meet the payroll. Cash received by enterprises from sales to the population is deposited with little delay in the bank. Almost all inter-enterprise transactions are financed by bank account transfers rather than in cash.

general methods used will be described briefly below. Details are contained in the appendix.

A. Turnover tax and profits: For the period 1935-41, turnover tax receipts and profits are broken down, in Soviet sources, by branch of industry and commissariat. These data are used to make rough estimates of the percentages originating in consumers' and producers' goods for these years. The results are extrapolated for years in which data are unavailable.

B. Social insurance and other indirect taxes: The breakdown of the social insurance markup by consumers' and producers' goods industries is based on Bergson's estimates for 1937.[22] The same relationship is used for other indirect taxes. This is an extremely crude expedient but no better method could be found.

Other indirect taxes include such items as customs receipts, tax on services, tax on cooperatives, local taxes on industry, and state income from timberlands. Detailed figures for each item are not available for all years; however since total other indirect taxes remained a fairly constant percentage (3 per cent) of budget income in the years for which the data are complete, this ratio was used to fill in the gaps.

C. Subsidy adjustments: Subsidies are subdivided into MTS subsidies and subsidies granted directly to enterprises operating at a loss.

The MTS subsidy for 1938-40 can be estimated directly from official data; estimates for 1937, and 1948 to 1950 were based on 1938-40 relationship and other scattered information (see appendix).

Direct subsidies to industry are derived as a residual figure. From Soviet sources it is known that the budget expenditure category "financing the national economy" includes the following expenditures: investment in fixed capital, investment in working capital, gross expenditures on the MTS, "operating" expenditures,[23] and subsidies. Estimates for the first three of these categories and for the total (financing the national economy) are available for the nonwar years since 1937. A residual comprising subsidies and operating expenditures can therefore be estimated. As operating expenditures are generally considered to be small, it is assumed that the entire residual is subsidies.

Most MTS activity is devoted to the production of food and industrial crops eventually purchased by the household. Therefore in making the deduction from taxes, it is assumed that two-thirds of the MTS subsidy applies to commodities purchased by the consumer; this amount is deducted.

[22] Bergson, "Soviet National Income and Product," Appendix, p. 11.

[23] Operating expenditures (*operatsionnye raskhody*) are expenditures on training workers, scientific research, and other projects administered by enterprises but not part of the normal operating expenses of production.

Soviet literature clearly indicates that the bulk of the general operating subsidies applies to nonconsumers' goods products. However, since subsidies to the coal industry and other raw materials and producers' goods affect the cost of consumers' goods, these should be taken into account. Accordingly, it is assumed that 20 per cent of general subsidies affect consumers' goods costs and are deducted from taxes. Not too much faith is placed in these adjustments and they are not included in our main series; crude as they are, however, the results achieved are not without interest.

Further Considerations

Soviet budget data are originally presented in plan form for the current year; in the subsequent year preliminary estimates of the actual results are published; another year later the final results are published. This is also true of most other financial magnitudes. As far as possible final and preliminary estimates were used; in many cases, however, planned figures were the only ones available and these were used. No distinction will be made between the preliminary and final estimates since they rarely differ by more than a fraction of one per cent; planned figures will be so designated (in the statistical appendix) and must be accepted with reservations.

III. *Statistical Results: "Burden" of Taxation*

Estimates of consumer money income (by outlay) for the periods 1925/6-40, and 1948-50, are presented in Table I. Sufficiently reliable data were not available for the period 1941-47. The estimate for 1931 probably understates consumer income by 15-20 per cent because of the huge illegal trade which occurred in this year and which is not reported in the retail turnover figure.

Three series of estimates of consumer taxes are presented in Table II. Series I, which covers the entire period from 1925/6-1940, and 1948-50 is unadjusted for (1) the turnover tax, profits, and other indirect tax data presented in the budget which are not paid by the consumer and (2) subsidies on consumers' goods. This series consequently overstates taxation of the consumer. Series II is adjusted for the taxes not paid by the consumer; the adjustment is not attempted for the period 1925/6-1929/30. Series III attempts an adjustment for subsidies to consumers' goods industries for the years after 1937. These latter two series, and particularly Series III, give a much closer approximation than Series I to the actual average rate of money taxation of the consumer; on the other hand, Series I enables us to observe the dynamics of tax policy in the New Economic Policy and First Five Year Plan periods.

Dividing each of the three taxation series by consumer income gives estimates of the average rate of money taxation. These are presented in Table III.

In the succeeding discussion of these ratios, the reader is cautioned to keep in mind that:

(a) Series I is not an actual rate of taxation but rather an index of the movement in the rate of taxation over time. Series II and III are better approximations of the actual rates of money taxation.

(b) These series do not include income in kind but do include part of taxation in kind. This leads to some overstatement of the average rate of taxation.[24]

(c) Many of the estimates upon which these series are based are crude.

IV. *Burden of Taxation: The United States and Soviet Union Compared*

The sheer size of the Soviet tax burden is the most striking result of the calculations summarized in Table III. That more than half, at times almost two-thirds, of personal income, should return to the state in the form of taxes is indeed revealing with regard to the importance of state activities in the Soviet economy. A perspective on the significance of the Soviet rate of taxation can be gained by comparing it with

[24] Taxation in kind takes the form of compulsory deliveries to state and cooperative procurement agencies by collective farms and individual farmers of a specified part of their crops at very low prices. These prices are a fraction of the retail price at which the state resells the same commodities to consumers and do not even cover cost of production. When the state resells these commodities, the difference between the cost to the state (procurement price plus the costs of processing and distribution) and retail price is usually siphoned into the state budget in the form of turnover tax. The portion of the turnover tax which is collected by virtue of a procurement price below cost of production is the monetary equivalent of part of the tax in kind. Another part of the tax in kind is, of course, invested directly by the state and is not reflected in the money tax statistics.

Bergson estimates consumption of farm income in kind to have amounted to 30 billion rubles in 1937 ("Soviet National Income and Product," p. 214). My own estimate for the tax in kind on grains in 1937 is 15 per cent; if this figure is assumed to be representative of all agricultural commodities in 1937, income in kind before tax is estimated to have been about 35 billion rubles. To this must be added 2.5 billion rubles in army subsistence (*Ibid.*). Thus total household income, including income in kind, is 37.5 billion rubles greater than our estimate of consumer money income (Table I), or 193 billion rubles. Taxes as computed in Table II are 43 per cent of total household income. However, as we noted above, taxes must also be increased to take into account that part of the tax in kind not reflected in the turnover tax. This would probably increase the average rate of tax by 3 or 4 points. Thus, for 1937, our estimate (Table III) of the average rate of taxation is probably 6 or 7 points higher than the true rate of taxation (in money and in kind). The adjustment for most other years would not be so great: because of the excellent harvest in 1937, the tax in kind was exceptionally small (discussed in Ch. 7 of my forthcoming book).

the rate of taxation in some western nation, and this will be attempted below.

TABLE III.—AVERAGE RATE OF MONEY TAXATION 1925/6–1950

(Per Cent of Consumer Income)

	1925/6	1926/7	1927/8	1928/9	1929/30	1931	1932	1933	1934
I	36.0	41.1	44.2	48.7	63.9	(72.2)	63.4	68.7	68.1

Sources: Derived from Tables I and II.

Because of the institutional differences between the Soviet Union and capitalist nations many consumer outlays which would not be included in taxes have to be included in this category in the case of the Soviet Union. For this reason the estimates of the average rate of taxation of the consumer computed in this chapter cannot be meaningfully compared with similar computations for other countries. In order to facilitate comparison, an attempt will be made to bridge the institutional gap, although the significance of such a comparison is admittedly very limited.

The procedure will be to estimate the total of taxes (*i.e.*, federal, state and local) on the consumer in the United States, defining tax on the consumer in the same way as it is defined in the Soviet Union. Thus, included in our total of taxes on the consumer will be the following unusual aggregates: purchases of government bonds by the public; the annual contribution to social insurance which is assumed to be entirely passed on to the household; undistributed corporate profits (because retained profits of Soviet industry were considered a tax) and sale of corporate securities to the population for purposes of financing new investment. The incidence of indirect taxes on business enterprises is assumed to fall entirely on the consumer. The estimates for the United States are presented in Table IV.

We see that the rate of taxation in the United States for the years 1940 and 1949 is less than half that in the Soviet Union, even when the United States' data are structured in accordance with Soviet institutional conditions. The difference between the Soviet and U.S. rates

reflects the much higher rate of nonconsumption expenditures in the U.S.S.R. The psychological burden of the taxation in the U.S.S.R. is undoubtedly greater, relative to the United States, than the figures would indicate because of the much lower level of real national income in the U.S.S.R.; this effect would tend to be offset, to some extent because the Soviets have never experienced higher standards of living,

TABLE IV.—AVERAGE RATE OF TAXATION IN THE UNITED STATES, 1940 AND 1949

(Billions of Dollars)

	1940		1949	
	Soviet Framework	Western Framework	Soviet Framework	Western Framework
A. Personal Income[a]	79.0	78.3	208.3	206.1
B. Taxation of household				
Direct taxes	2.6	2.6	18.7	18.7
Indirect taxes	10.0	10.0	21.3	21.3
Purchases of government bonds	.5		4.3	
Social Insurance	2.3		5.7	
Undistributed corporate profits	2.4		9.8	
Sales of new corporate securities[b]	.6		4.6	
Total taxes (B)	18.4	12.6	64.4	40.0
Average Rate of Taxation (B÷A)	23.3	16.1	30.9	19.4

Sources: *Treasury Bulletin*, published monthly by the United States Treasury Department; *Survey of Currency Business*, published monthly by the United States Department of Commerce.

[a] Each American worker pays, out of his own gross wage, part of the social insurance contribution made in his name. Since we view the social insurance contribution as a tax in the Soviet framework, we consider the workers' contributions an addition to income. This accounts for the difference between personal income figures for each year.

[b] Sale of new corporate securities does not include securities which were issued for the purpose of refunding previously issued securities.

because so large a part of their income is taken away in the form of higher prices rather than as direct levies upon income,[25] and because their marginal tax rates appear to be relatively low.

V. *Alternative Measurements of the "Burden"*

The burden of Soviet taxation as computed above is based on a rather arbitrary definition of what constitutes a tax on the Soviet population. For this reason, three other measurements of the average rate of taxation will be presented and briefly discussed; the first two constitute an approximation to measuring the Soviet burden of taxation in a capitalist institutional framework.

[25] *Cf.* Holzman, *op. cit.*, pp. 425-27.

The rates of taxation presented in Table III are on the "high" side. For reasons discussed above, certain elements of the Soviet cost-price structure have been considered as taxes although they contain elements of factor cost. For example, profits have been considered a tax rather than a return to capital or as a reward for exceptional entrepreneurial ability. And the social insurance markup has been considered a tax when a case could be made for treating it as an addition to wages. We have also treated sales of government bonds to the population as a tax although such sales should be classified somewhere in between taxes and "truly voluntary" sales of government bonds. Therefore, we present below some alternative estimates of the burden of Soviet taxation, leaving the reader to his own preference.

In the first alternative estimate, both sales of government bonds and the social insurance markup are eliminated from the total of taxes as computed in Series II of Table II. The resulting figures, divided by total income, are designated Series IV in Table V below. If the reader desires to add the subsidy adjustment of Series III, this can be approximated roughly by simply deducting from Series IV, the difference between Series II and III (in Table III).

In the second estimate, retained profits are added to sales of government bonds and the social insurance markup; and all three items are deducted from the total of taxes (II) and divided by total income. The resulting ratio is designated Series V.

The third modified series (VI) is conceived in terms of a very crude benefit theory of taxation. Budget expenditures on education and health services are deducted from the total of taxes on the ground that the household benefits directly from these expenditures in contrast to other budget expenditures (investment in the national economy, defense, administration, etc.) which either do not benefit the household directly, or at all. In addition, transfer payments (*e.g.*, social security, social insurance,[26] subsidies to mothers, and the debt service) are removed from both the income and tax series. Although taxation to finance transfer payments is not without its psychological burden, the impact of such taxation is certainly offset in part by the distribution of the various transfer payments.[27]

[26] Social security includes pensions and other assistance, upkeep of invalid homes, rehabilitation of injured workers, etc. Social insurance includes insurance for sickness, unemployment and old age.

[27] One justification for this approach is that the Soviet government does finance a relatively large program of social services (educational, medical) and transfer payments. Objections can be raised against the deduction of budget expenditures on education from taxation. It may be contended that a part of these expenditures cannot be considered to benefit the population directly since it serves to finance communist propaganda, the press,

In this series (VI), as in the case of Series IV and V, a rough adjustment for subsidies to consumers' goods industries can be made by the reader. The three new series are presented in Table V attached.

It can be seen in Table V that the average rate of taxation is very high even after the above-mentioned adjustments are made. Deducting the social insurance markup and sales of government bonds from total taxes (IV) reduces the burden by only seven to eight percentage points on the average. Deducting, in addition, the retained profits of state enterprises (Series V) reduces the burden by about another 3 points on the average. With all these deductions, the average rate of taxation exceeds 46 per cent in the postwar period.

The burden is reduced by as much as one-third to two-fifths when education and health services are deducted from taxes, and transfer payments are removed from both income and taxes. The average rate of tax, even with this generous interpretation, still ranges between 35 and 50 per cent of income.

It is of interest to attempt to answer the question: to what extent did increases in the rate of taxation serve to finance increased social services and transfer payments to the population. For this purpose, the ratio of the total of budgeted expenditures on health, education, and transfer payments to total taxes (Series II) was calculated; the results are presented as Series VII in Table V. The ratio declined from 1932 to 1933 but increased thereafter until 1937 with a large jump occurring from 1935 to 1937. In other words, an increasing share

---

scientific research, a part of which may be directed at constructing atom bombs, and so forth. There is undoubtedly substance to this objection.

It does not appear to be feasible, however, to draw a sharp distinction (particularly in terms of budget expenditures) between education and propaganda in the Soviet Union (or in most other countries).

Since 1949, and perhaps earlier, expenditure on scientific research has been presented in the budget as a separate category, alongside of education, under the more general heading: social and cultural expenditures. From 1949 to 1951, the separate expenditures on science amounted to roughly 10 per cent of expenditures on education (*cf.* Finance Minister Zverev's recent budget speeches). This provides an indication of the possible extent of expenditures on scientific research when they were included under education. It does not exclude the possibility, of course, that large outlays for atomic and other research are still included under education. Unfortunately, there is, to my knowledge, no reliable information on this matter.

Since 1949, expenditures on the press, theatres, etc. have been included in the budget under education only to the extent that the separate enterprises are not self-financing. *Cf.* N. N. Rovinskii, *Gosudarstvennyi biudzhet SSSR* (State Budget of the USSR), Moscow 1949, p. 292. Before 1949, gross expenditures on these categories were financed by the budget. I am not sure whether or not budget expenditures on education are net of receipts from tuition fees. If not, there is an overstatement of expenditures on education from this source.

TABLE V.—AVERAGE RATE OF MONEY TAXATION RECOMPUTED, 1932–1950
(in per cent)

	1932	1933	1934	1935	1936	1937	1938	1939	1940	1948	1949	1950

Sources: See appendix (fn. 18).

of taxes on the consumers returned fairly directly to the population in this period, and less was devoted to other nonconsumption items (*e.g.*, defense, investment, administration). In 1939, as the Soviets prepared for war, this trend was sharply reversed. From 1948 to 1950, the relative importance of expenditures on social services was once again on the rise, and by 1950 had almost reached the 1937 percentage level.[28]

VI. *Trends in the Burden of Taxation*

In this section, changes in the average rate of taxation are treated as an indicator of changes in the rate of nonconsumption as well as of the psychological burden of taxation. For this purpose it is important to note that the average rate of taxation is affected by changes in the degree of repressed inflation in the state sector of the economy.[29] Increases in repressed inflation are reflected in higher prices in the collective farm markets, hence in larger household incomes from sales (or expenditures) in these markets. At the same time, an increase in repressed inflation is indicative of too low a rate of taxation to support the rate of nonconsumption presumed by the state investment plan. So when repressed inflation is on the rise, taxes tend to be understated, household income overstated, and the burden (taxes/income) therefore understated relative to the burden which would obtain if taxes were large enough for fiscal stability. Conversely, when repressed inflation is being reduced, the burden of taxes tends to be overstated. If the effects of repressed inflation could be removed from the ratio of taxes to income, the resulting series would obviously be a better index of changes in the rate of nonconsumption (though not, perhaps, of the psychological burden of taxation) than the unadjusted series presented above in Table III.

If the *volume* of trade on the collective farm markets had remained relatively constant, then it would be possible to remove a large part of the effect of changes in repressed inflation by deducting from the household income series, income from sales on the collective farm markets. Unfortunately, the volume of trade on these markets did not remain constant. Sales were gradually wiped out between 1927 and 1931 as the state attempted to liquidate (what was then called) private

[28] We have made no adjustment here for the fact that a ruble used to buy a unit of equipment is probably worth a lot more than a ruble used to buy a unit of education or health. *Cf.* N. Jasny, "The Soviet Price System," *Am. Econ. Rev.*, Dec. 1950, XL, *passim*.

[29] By repressed inflation we mean simply that the amount of goods the household would like to buy from state and cooperative stores at going prices is in excess of the amount offered for sale. This excess demand typically spills over into the collective farm markets (where price is set freely by supply and demand) raising prices in these markets above those in state and cooperative stores.

trade; the collective farm markets were reconstituted in 1932 and the volume of trade rose steadily from 1932 to 1939, and perhaps to 1940. For this reason, no attempt will be made to quantify the impact of repressed inflation on the average rate of taxation; this distorting effect of repressed inflation will be taken into consideration, however, in the discussion which follows.[30]

The First Five Year Plan Period

Series I shows a continuous increase in the rate of taxation from 1925/6 until 1929/30; the rate of increase is fairly constant with the exception of 1929/30 when a big jump upward occurs. These five years include the last three years of the NEP and the first two years of the First Five Year Plan. The figures indicate that during the last three years of the NEP the state was not just marking time until the blueprints for a planned economy were completed and ready to be put into operation; on the contrary the state was annually pre-empting larger percentage shares of the nation's output.

It is interesting that the first year of the plan period (1928/29) does not mark a sharp break with the preceding period; it is not until 1929/30 that the full impact of the industrialization drive is felt by the population. This seems to be in accord with other available information. It was originally planned that the net rate of investment would be 22.6 per cent in 1928/29 in comparison with 18.9 per cent in 1927/28, and 25.1 per cent according to the minimal variant or 28.2 per cent according to the optimal variant in 1929/30.[31] Apparently progress in 1928/29 was sufficiently satisfactory to warrant raising the target for investment for 1929/30 by about one-third over the original plan.[32] This combination of facts seems to indicate that only a moderate

[30] Other modifications would be in order if we were particularly concerned with determining the Soviet rate of nonconsumption.

A closer approximation to the actual rate of nonconsumption is obtained by removing transfer payments from both the income and tax series. This has the effect of reducing the ratio of taxes to income, but leaves the trend from year to year relatively unchanged.

It would also be appropriate, in attempting to determine the actual rate of investment, to add to the total of taxes, increments (decrements) to currency in circulation. For to the extent that taxes, profits of nationalized industry, and receipts of the state from other sources are insufficient to cover Soviet nonconsumption expenditures (including those financed by short-term bank loans of the *Gosbank*) the government introduces new currency into circulation. Including changes in currency in circulation with taxes has the effect, in most years, of increasing the ratio of taxes to income, but with the exception of the years 1932 to 1934 it does not affect the trend.

Since we are primarily concerned with the rate of taxation of the population neither of the above adjustments is made, nor are certain other minor sources of financing investment taken into consideration.

[31] M. Dobb, *Soviet Economic Development Since 1917* (London 1948), p. 236.

[32] *Ibid.*, pp. 242-43.

rate of increase was planned for 1928/9 relative to 1927/8, and that a much sharper increase probably occurred in 1929/30. Our figures are in accord with this and, if anything, suggest an even sharper shift to nonconsumption in 1929/30 than was contemplated in the revised plan.

The large increase in the rate of taxation in 1931 may be largely spurious. By 1931 all legal private trade had been abolished, and it was not until mid-1932 that the collective farm markets were legally organized. In the interim a large amount of illegal private trade is reported to have been conducted, the value of which was not included in the official figures.[33] Furthermore, to the extent that peasants found it difficult to conduct trading operations, consumption in kind was probably increased. Both of these factors would operate to cause our rate of taxation to be spuriously high in 1931, the first by reducing computed consumer money income, and the second by causing a real shift from consumption of marketed commodities to consumption in kind.

Some illegal trade may also have been conducted in 1929/30 and our tax rate for that year may be high. However, even if the illegal trade were taken into account, an extraordinary increase in the rate of taxation would probably still have occurred in 1929/30; and the rate for 1931 would probably fall somewhere between the rates for 1929/30 and 1932.

Repressed inflation increased steadily from 1928 to 1932, and collective farm market prices are reported to have reached a peak in 1932.[34] Prices of some foods were 15 times the ration prices of comparable goods sold in cooperative stores.[35] The growth of repressed inflation in this period implies that the share of the government sector in the national output was growing even more rapidly than the average rate of taxation series indicate.

Second and Third Plan Periods

From 1932 to 1936, the average rate of taxation increased slowly,

[33] The figures for retail trade turnover are broken down as follows:

	1929/30	*1931*	*1932*
State	4.1	6.5	15.5
Cooperative	12.4	18.2	25.8
Kolkhoz	—	—	7.5
Private	1.1	—	—

[35] Sh. Turetskii, "Puti planivoraniia tsen" (Methods of Price Planning), *Planovoe khoziaistvo* (Planned Economy), 1936 No. 3, p. 130.

by a few points a year, on the average. As an indicator of the rate of nonconsumption, this increase has an upward bias due to the fact that from 1933 to 1937, repressed inflation was being gradually worked off. In 1933, repressed inflation is reported to have declined by about 50 per cent;[36] prices of agricultural products declined by 20 per cent in 1934 and 12 per cent in 1935 and by December 1936 had reached a level which was from 1/3 to 1/3.3 of the 1932 level.[37]

It is not possible to state with confidence whether the absolute level of consumption from marked output rose, remained the same, or declined from 1932 to 1936. The standard of living could have risen if national output per capita was increasing at a faster pace than the rate of taxation (nonconsumption); or fallen if national output had remained the same or declined. Soviet indexes of output and productivity for industry both show unusually rapid increases beginning in 1933;[38] the output of the major crops also increased from 1933 to 1935, with a sharp decline in 1936, however.[39] All in all, the indications are that some increase in living standards probably occurred from 1932 to 1936.

The situation from 1936 to 1938 is unambiguous: the share of consumer income absorbed by taxes declined by 6 to 7 percentage points, fairly conclusive evidence of a rise in the consumers' share in the national output. These figures are in accord with the fact that the 1937 harvest was exceptionally good, undoubtedly affecting the level of consumption in both 1937 and 1938.

In 1939 and 1940, the rate of taxation increased as rapidly as it had declined in the previous two years. This increase reflects preparations

[36] *Ibid.*, p. 133. There was a sharp decline in the amount of currency in circulation in 1933, certainly circumstantial evidence that a deflationary policy was being pursued. The movements of other financial magnitude indicate a similar policy. It is interesting to note that if we included the change in currency in circulation along with taxes in computing the average rate of taxation (as suggested in fn. 30), the trend in the rate of taxation for the years 1932 to 1934 is altered as follows:

	1932	*1933*	*1934*
Series II, unadjusted	51.0	55.9	55.8
Series II, adjusted	55.8	53.5	56.9

The rate of tax is spuriously low (as an indicator of investment) in 1932 because of the increase in repressed inflation, and spuriously high in 1933 because repressed inflation was being reduced.

[37] *Ibid.*, pp. 133, 136; Lifits, *op. cit.*, p. 319.

[38] *Cf.* A Gerschenkron, "The Soviet Indices of Industrial Production," *Rev. Econ. Stat.*, Nov. 1947, XXIX, 218; W. Galenson, "Russian Labor Productivity Statistics," *Indus. Lab. Rev.*, July 1951, IV, 500. The indexes computed by Donald Hodgman (as yet unpublished), presumably free of the specific Soviet weighting bias, bear out the statement in the text.

[39] Jasny, *The Socialized Agriculture of the U.S.S.R.* (Stanford, 1949), p. 792.

for war[40] which apparently were begun in earnest in 1939, and the smaller harvests in these years. It is surprising that the rate of taxation increased by less than 2 points in 1940 compared with 1939 in view of the threatening international outlook and need to prepare for war. Two developments may explain this low figure: First, a substantial part of increased defense needs were met by a cutback in expenditures on the national economy, particularly industry.[41] Second, repressed inflation appears to have been on the rise again in 1940 so that the change in the average rate of taxation probably understated the increase in the rate of nonconsumption.

Postwar Period[42]

The figures for the postwar period are very interesting. In 1948 the average rate of taxation was higher than in any prewar year; about 65 per cent of consumer money income was handed over to the government in the form of taxes (Series III). In 1949, the average rate of taxation declined by one percentage point; and in 1950 by about 6 percentage points . . . almost down to the 1940 rate of taxation. These reductions reflect the much publicized consumers' goods price cuts of March 1, 1949 and March 1, 1950.[43]

The principal implication of this decline in the rate of taxation is that in 1950 the consumer was getting a substantially larger share of the national output than in 1948; and since national output was undoubtedly increasing in this period, a very large percentage increase in real income. Although this may be difficult to accept in view of the tense international situation and the popular conception of a Russia arming to the teeth, it is not unreasonable.

The rate of taxation in 1950 is not low even by Soviet standards. In fact it is higher than the rate of taxation in the last prewar year, 1940, a year in which maximum peace-year preparedness efforts were being made. And in 1948 the rate of taxation was 8 to 9 per cent higher than in 1940. The reasonable interpretation, it seems, would be to consider the 1948 rate of taxation abnormally high, reflecting a structure of pro-

[40] The proportion of budgeted defense expenditures to total budgetary expenditures increased from 18.7 per cent in 1938 to 25.6 per cent in 1939 to 32.5 per cent in 1940.

[41] From 1939 to 1940, absolute expenditures on the national economy and on industry fell from 60.4 billion rubles to 58.3 billion rubles, and from 31.1 to 28.6 billion rubles, respectively. Since total budgetary expenditures were increasing, the percentage (of budgetary expenditures) declines was much greater: from 39.4 to 33.4 per cent, and 20.3 to 16.4 per cent.

[42] Soviet sources indicate that there has been little or no repressed inflation since the currency reform of December, 1947.

[43] See Moscow newspapers of March 1, 1949 and 1950.

duction not yet returned to normal after the war; and the decline in taxation from 1948 to 1950, a return to normalcy.

There are special reasons for expecting an increase in consumers' goods output in this period. During the war years consumers' stocks and reserves must have declined to an incredibly low level and provision had to be made for restocking. Furthermore, the morale of the population may have been at a low ebb after a difficult war and many years of privation; the reduction in rate of taxation may have been required for reasons of internal political stability. Finally, it should be noted that the shift in the distribution of national output toward the consumer does not at all imply that the absolute amount of resources devoted to investment, defense, etc. declined; increases in the output of consumers' goods probably were met largely out of increases in productivity and total output.

THE CYCLICAL TURNING POINTS IN AN "OPEN" ECONOMY: CANADA, 1927-1939

By EDWARD MARCUS*

Very little theoretical or empirical work has been devoted to studying the *international* transmission of the business cycle. As Morgenstern has said, "We do not have too much knowledge about the working of a business cycle in a closed economy, but we know even less about the transmission of cycles from one country to another . . . the few explanations of the international transmission offered currently are very tentative and appear more or less as mere appendixes to, or extensions of, specific cycle theories.'[1] It is with these international aspects that this article will deal, particularly as illustrated by the Canadian economy in the decade before World War II.

In general, the degree of vulnerability of an economy to external influences is assumed to vary with the dependence on foreign markets; the less self-sufficient the economy, the more sensitive it is to changes in business activity abroad. Such a relationship, however, does not always hold; Canada, for example, displayed some independence of movement during the interwar years, particularly at the peak of the cycle. In both 1929 and 1937 her downturn preceded those of the cycles in her two main external markets, the United States and Great Britain. Here world economic forces of a more general nature, rather than cyclical, tended to dominate the course of the Canadian economy. These forces arose from the many intangible commercial ties that are a concomitant of an extensive foreign trade; they reflected the impact of changes that result from shifts within specific markets for Canadian products.

On the other hand, the Canadian upturns from the troughs of 1932-1933 and 1937-1938 were clearly the response to similar moves within the economies of her two main customers. Only after the American and British recoveries had begun was Canadian business activity stimulated sufficiently to follow along.

These four turning points will now be examined more closely, with particular emphasis on how the relative importance of domestic and international circumstances affected their timing.

I. *The 1929 Downturn*

Although the period 1927-1929 was a prosperous one, symptoms of the forthcoming decline appeared early. Prices of the main Canadian exports—wheat and wheat flour, wood pulp and newsprint—started to sag in 1927 and 1928; an oversupply was slowly building up, and the volume of exports started to waver. Gradually, the effects on incomes and purchasing power accumulated, and other sectors of the economy ended their upward movement. As the declines spread from the main exports to production and incomes, secondary indices, such as those of the supplying industries, employment, and distribution followed.

The Canadian economy thus turned down several months before the American turning point occurred. This is not surprising, for Canada was far less industrialized, more dependent on agriculture and forestry products. Since the 'twenties were not a period of great prosperity for those industries compared with the manufacturing areas, the earlier downturn of the raw material sectors found a more vulnerable situation in Canada. Manufacturing was not so large that it could sustain an over-all prosperity, such as continued south of her border for several months more.

After the first World War, a situation of overproduction had gradually emerged in industries exploiting natural resources. Per capita wheat consumption was dropping while production was recovering.[2] In the Canadian newsprint and pulp industries the danger was all on the side of a too-rapidly increasing supply. From 1927 to 1929 installed capacity increased by one-sixth, and the operating ratio tended to remain within the range of 80 to 85 per cent of rated capacity.[3]

The danger first showed up in a weakening of the price structure. From mid-1927 to mid-1929 the Stanford University Food Research Institute's weighted average of Winnipeg cash closing prices of ten grades of Canadian wheat dropped more than 30 per cent, from $1.47 to $1.01 per bushel. The Canadian visible supply started to climb as a result of a wheat crop 80 million bushels more in 1927-1928 than in 1926-1927. World wheat stocks registered the largest annual increase

[2] *Cf.* B. Ohlin, *The Course and Phases of the World Economic Depression*, rev. ed. (League of Nations, Geneva, 1931), pp. 21, 39, 45, 49, 93, 124-25.

[3] *Cf.* E. A. Forsey, "The Pulp and Paper Industry," *Can. Jour. Econ. Pol. Sci.*, Aug. 1935, I, 502; Ohlin, *op. cit.*, p. 59; C. E. Fraser and G. F. Doriot, *Analyzing Our Industries* (New York, 1932), p. 317.

since the war. Wheat flour prices dropped almost 20 per cent during the same period. Wood pulp prices also declined, particularly in 1927, groundwood—Canada's main wood pulp export to the United States—going from $1.50 per 100 pounds in the first quarter to $1.15 in October.[4]

In 1928 the volume of Canadian wood pulp exports, particularly to the United States, ended their upward trend, and in some months even registered declines. Since 80 per cent of these exports went to the United States, and since the main form—groundwood—was used to make newsprint, we would expect the export movement to follow that of American newsprint production. In contrast to the Canadian newsprint industry, the American output was declining, the average for 1928 having dropped more than 15 per cent below 1926. Not protected by a tariff as was the rest of their paper industry, American producers were being forced out of newsprint into tariff-protected high quality paper manufacture, using other pulp, particularly the chemically prepared types. In addition, the use of chemical pulp was becoming of increasing importance in the manufacture of paper and paperboard. In short, the American demand for wood pulp was shifting from groundwood, of which over 90 per cent of the imports were supplied by Canada, to the chemical pulps, for which Canada was a much less important supplier—of only about one-third of the imports.[5]

In 1928 the growing overcapacity in the newsprint industry brought on a disastrous price war. Started by negotiations over the renewal of the large Hearst newspaper chain contract with International Paper, the price war spread to all companies. Contract prices dropped a quarter in the summer months. However, since the volume of newsprint consumption was a resultant of the circulation and advertising linage of the newspapers,[6] and since both the newspaper newstand prices and advertising rates were unchanged, despite the lower news-

[4] Data from readily available publications have not been cited. In general, export figures are from *Trade of Canada;* wheat statistics from the Food Research Institute, *Wheat Studies;* Internal (Canadian) series from the Dominion Bureau of Statistics, *Mo. Rev. Bus. Stat.* (since replaced by the *Can. Stat. Rev.*); U.S. statistics from the *Surv. Current Bus.*, the *Fed. Res. Bull.*, and the *Mo. Summary For. Commerce;* British import data from the *Accounts Relating to Trade and Navigation.*

[5] Most of the information on the pulp and paper industry is drawn from J. A. Guthrie, *The Newsprint Paper Industry* (Cambridge, 1941); and contemporary accounts in the *Monetary Times* (Toronto), the *Financial Post* (Toronto), *Editor and Publisher* (New York), and the *Economist* (London).

[6] Newspapers usually maintain a fixed ratio of each issue's advertising to total space. A change in the advertising volume would thus alter the size of the individual issue and therefore the quantity of newsprint per copy. A change in circulation would vary the number of newspapers sold and thus, again, the volume of newsprint consumed. Hence, changes in either affected the publishers' demand for newsprint.

print costs,[7] the drop in newsprint prices resulted only in curtailed revenues for the manufacturers, rather than a jump in sales volume. This was reflected in share prices, the newsprint firms' securities dropping 40 per cent during the period of the price war, while the average of all Canadian industrials rose 30 per cent.

What undoubtedly postponed the downturn at this point was the inflationary influence of the banks. At this time they were pursuing an expansionary policy despite the outflow of gold to the United States; this latter movement was the result of a greatly increased adverse trade balance, as imports rose with increased prosperity at home, producers' goods imports, in particular, responding to expanding investment demands within Canada. Yet, despite this drain on reserves, the banks continued to expand loans and deposits; in part this resulted in lower reserve ratios for the banks, and in part the deficiency was met by increased borrowing from the Dominion government under the Finance Act.[8] This borrowing, in turn, resulted in a gold outflow from the reserves backing the Dominion notes; in January 1929 Canada abandoned the gold standard *de facto* by placing an embargo on gold exports.[9]

Another inflationary influence was the "wheat holdback" in 1928-1929. The 1927-1928 crop had been very good, and prices had declined. As 1928 wore on, however, the outlook for the next crop was not promising. Since it was felt that European millers were dependent on the high-grade Canadian wheat for milling flour, and since it was thought that there would be a shortage of these quality grades, many Canadians believed that a sizable price rise for these particular strains was inevitable.[10] The Wheat Pools, private traders, farmers, millers, and speculators all shared this view. Hence, a holding movement developed in Canada, moving Canadian wheat prices out of line with world prices of competing wheats, the normal premium in the Liverpool market doubling. Much of this holdback, of course, was financed through the Canadian banks.

[7] Actually, some advertising rates were raised during this period. *Cf.* the *Editor and Publisher International Year Book for 1935* (New York, 1935), p. 106.

[8] The method of borrowing and the effects on the banks' reserves were analogous to U.S. member bank borrowing from the Federal Reserve Banks, although at that time the Canadian banks did not have a central authority holding their reserves.

[9] For a more complete story of this episode, see V. W. Malach, "The Mechanism of Adjustment in Canada's Balance of Payments, 1921-9," *Can. Jour. Econ. Pol. Sci.*, Aug. 1952, XVIII, 313-15; C. A. Curtis, "Credit Control in Canada," Canadian Political Science Association *Papers and Proceedings II*, May 1930, especially pp. 109 ff.; and my (unpublished) doctoral dissertation, *Economic Fluctuations in Canada, 1927-1939* (Princeton University, 1950).

[10] This discussion is based on contemporary material, especially in *Wheat Studies* and the *Economist*.

The results were disastrous. During the latter half of 1928 and throughout 1929 there was an almost perfect inverse movement between the premium on Canadian wheat and the percentage of British imports of wheat coming from Canada; the larger the premium, the lower the Canadian share of British orders. This adverse effect on Canadian wheat exports started with the holdback in 1928; in the last quarter of that year Great Britain, the Netherlands, Switzerland, and Belgium started to curtail their purchases of Canadian wheat. Canadian flour exports also lagged, since the main constituent (Canadian-grown wheat) had risen so sharply in price; foreign competitors had turned to cheaper grades. In fact, in protest against the control of sales in Canada, British importers and millers extended a definite buying preference to Argentine and Russian wheat.[11] The resulting decline in exports and increase in stocks of wheat and wheat flour were far more than the Canadians had anticipated.

The curtailment of these exports reacted back on farm purchasing power, and after Christmas 1928 rural spending dropped off.

As the effects of the various deflationary forces cumulated—the decline in wood pulp exports and prices, the newsprint price war, and the wheat holdback—they began to be reflected in total spending. After the first quarter of 1929 bank debits, which had been exceeding the corresponding months of 1928, started to decline. The drop in wheat and wheat flour exports hit steamship and railroad earnings, as well as the textile industry through lessened demand for flour sacks. Both newsprint and wood pulp exports, particularly to the United States, also were below the previous year. As the declines spread, other industries reacted. Pig iron production dropped in March. Construction contracts, which had been running ahead of the previous year, dropped below in April and May 1929.

At the end of March stock prices broke sharply both in Canada and the United States, Canadian prices declining much more. As though touched off by this shock, series after series started to waver or turn down in Canada, and even in the United States a few started to recede. From April on, the chronicle is a dreary repetition of recession in the individual Canadian indices. The downturn was now well under way, to be followed in June by the United States.[12]

II. *The 1932-1933 Recovery*

The downward movement of the Canadian economy, like that of most of the world, continued almost without interruption for more than the first two years after the 1929 peak. Production and incomes fell, unemployment rose, and the dreary pall of stagnation enveloped the entire country. Since her two main customers—Great Britain and the United States—were depressed, it was inevitable that Canada should be similarly affected.

It was this dependence on two different economies, however, that finally put a bottom to the recession. It will be recalled that each of Canada's two main export groups depended greatly on the demand in one of these countries—wheat and wheat flour on the British demand, wood pulp and newsprint on American demand. While both customers were in the downward phase these two export groups were not prosperous, of course. But with the 1932 upswing in Great Britain,[13] the wheat indices improved, along with those parts of the Canadian economy whose main market was also in Great Britain. Hence, offsetting the continued downward pull of the American market was the upward movement of the British; as a result, the Canadian economy tended to level off in 1932. Then, in the following spring (1933) the American economy turned up sharply, accompanied by Canada. With both the British and American recoveries as supports, the Canadian indices then were, almost without exception, in the revival phase.

Although we have not emphasized the impact on the Canadian balance of international payments, it might be noted that its cyclical behavior also made for a certain degree of maneuverability during the depression period. Because of the importance of producers' goods imports, a recession within Canada would reduce domestic investment sharply, thus tending to cause a drop in imports greater than was developing in her exports (as a result of other countries' recessions), thus improving the current account position. This improvement offset the accompanying drop in the inflow of (mainly American) capital funds, thus averting serious pressure on domestic banking and currency re-

p. 78, and the 30th Annual Report of the National Bureau of Economic Research, *New Facts on Business Cycles* (May 1950), chart 4 (p. 11).

[13] Immediately after her departure from the gold standard British financial policy, fearing inflation, pursued a restrictive program, preventing any inflationary boomlet, such as occurred in the United States in the spring of 1933. The Bank Rate was raised to 6 per cent on September 21, 1931, and was kept at that level until February 18, 1932. Hence, it was not until several months after the ending of the external pressure on the pound sterling that internal recovery was permitted to get under way. For a summary of British policy and events during this period, *cf.* H. Heaton, *The British Way to Recovery* (Minneapolis, 1934), Ch. 4.

serves, minimizing the foreign exchange difficulties that plagued so many other debtor nations.[14]

If we examine the general indices, we can see the decline slackening by 1932. Manufacturing production, which had dropped almost continually from its April 1929 high of 117.7 to 59.0 in April 1932, rose to 72.8 in June, then gradually receded to 62.2 at the end of the year, and to 52.0 by February 1933.[15] Mineral production dropped from 75.8 in April 1929 to 47.3 in August 1932, the depression low, recovering during the remainder of the year. The low for exports (excluding gold) to Great Britain (in terms of Canadian dollars) was reached in 1931, January 1932 exceeding the previous January by almost $2 million, or 25 per cent. Exports to the United States, of course, remained low until the recovery in the spring of 1933.

It will be recalled that in the preceding prosperity warning signals could be detected some two years before the actual downturn. Moreover, these signs of weakness were applicable particularly to the Canadian economy, centering about its own products—wheat and wheat flour, wood pulp and newsprint. No important world event prior to the summer of 1929 influenced significantly the course of Canadian economic activity. In contrast, the 1929-1933 period was one of almost uninterrupted decline, stopped only by external events whose influences were world-wide—the recovery in business activity in the United States and Great Britain, and the resulting revival in Canadian exports to these two. These two developments were powerful enough to reverse the course of Canada's domestic cycle.

The relation of the 1932-1933 cyclical turn in Canada to the movements of the British and American cycles can be seen by examining the foreign exchange movements. In the months following the widespread departures from the gold standard in the autumn of 1931, the British pound declined much more than did the Canadian dollar. Hence, during that period the pound was depreciated in terms of both the Canadian and American dollars, while the Canadian dollar was depreciated in terms of the American dollar; in other words, temporarily, Canada had a competitive exchange position that was advantageous relative to the United States but disadvantageous relative to Great Britain. Yet, in 1932, it was in the British market that Canadian exports started

[14] For a more extended discussion of the external adjustment, *cf.* E. Marcus, "The Cyclical Adjustment Pattern of an 'Open Economy': Canada, 1927-1939," *Econ. Jour.*, June 1952, LXII, 305-17.

[15] 1935-1939 equals 100. Source: *Mo. Rev. Bus. Stat.* This movement was similar to the course of industrial production in the United States. The Federal Reserve Board index declined from its September 1929 high of 116 to 52 in July 1932, rose to 62 in October 1932, then dropped back to 55 by the end of the year and to 54 in March 1933 (1935-1939 equals 100, unadjusted index).

to recover, while shipments to the United States continued declining as a result of the continued drop of economic activity there. The drop of the Canadian dollar in New York, from September 1931 to April 1933, did not counteract the depressing effects of the receding activity in the United States, whereas the British recovery, and accompanying rise in domestic purchasing power, were strong enough to offset the effects of the depreciation of the British pound in terms of the Canadian dollar. On the other hand, in the spring of 1933, the U.S. dollar dropped sharply, in terms of the Canadian dollar (and other currencies); despite this apparent exchange disadvantage to Canada, the accompanying rise in U.S. incomes in response to the various New Deal measures resulted in a sharp rise in Canadian exports to the United States.[16] In both periods, it was the domestic incomes, rather than the foreign exchange price effects, that dominated the movement of Canadian exports.

Coincident with the British recovery the turning point in many Canadian export indices occurred in mid-1932, particularly those for the sterling bloc markets—foodstuffs, nonferrous metals, and automobiles. Because of the particular commodity markets first receiving this stimulus, the geographical distribution of recovery in Canada was initially uneven, the Prairie Provinces (Alberta, Saskatchewan, and Manitoba) experiencing more benefit than Quebec, where the wood pulp and newsprint industries were still suffering as a result of their dependence on the U.S. market. For example, bank debits in the Prairie Provinces in 1932 were only 8 per cent below 1931, whereas in Quebec they were almost 21 per cent lower.

Then, in March 1933, the American recovery began. This aided Canada both directly, because of the increased buying by Americans, and indirectly, the intangible currents of American business psychology spreading northward across the border. This almost immediate reaction can be seen readily in the export statistics. In the first four months of 1933 Canadian [redacted] the United States (excluding gold) were almost 40 per cent below the first four months of 1932; in May-June they were only 3½ per cent less; and in July 1933, 42 per cent higher than in July 1932.

Practically every important Canadian index that had not turned up with the 1932 British upswing recovered in the 1933 American boomlet.[17] The almost unanimous agreement in timing of the American and Canadian series is obvious; only newsprint exports lagged, because

[16] For a somewhat more extended discussion, *cf.* Marcus, "The Cyclical Adjustment Pattern of an 'Open Economy,'" *loc. cit.*, pp. 308-11.

[17] The immediate and widespread influence of the U.S. upturn is seen in the sharp reversal from decline to rise in almost everyone of the forty leading indicators of Canadian economic activity in the months after the start of the New Deal.

American newspaper advertising, and thus newsprint consumption, lagged until the last quarter of the year.[18] In common with most of the world Canada was starting the climb up the business cycle again.

III. *The 1933-1937 Upswing*

During these years Canada enjoyed an upswing, although not back to full employment. The mining industry led the recovery, while wheat was a conspicuous laggard.

The expansion of mining output was paced by gold. The rise in its Canadian dollar price after the 1931 departure from the gold standard while production costs were falling furnished a strong stimulant. Moreover, since Canadian gold was frequently found in conjunction with other metals, production of these others also rose, aided by an expanding British demand for housing, and later for rearmament. Moreover, many mining companies had completed large-scale programs aimed at achieving greater efficiency; these had been initiated before the 1929 depression broke, but the resulting reduction in costs could now be reflected in a quickly increased output.[19]

The partial replacement of wheat exports by the mines' output is shown strikingly in the annual figures in Table I.

TABLE I.—CANADIAN EXPORTS

(Annually; millions of Canadian dollars)

Year	Wheat and Wheat Flour	Percentage of 1928 Exports	Non-monetary Gold[a]	Percentage of 1928 Exports	Selected Nonferrous Metals[c]	Percentage of 1928 Exports
1928[b]	$498	100.0	$ 40	100.0	$ 66	100.0
1933	142	28.5	82	205.0	51	77.3
1934	150	30.1	114	285.0	66	100.0
1935	156	31.3	119	297.5	84	127.3
1936	237	47.6	132	330.0	103	156.1
1937	182	36.5	115	[redacted]	[redacted]	230.3

[a] Newly mined gold.

[b] 1928 rather than 1929 was selected, because of the wheat holdback in the latter year.

[c] Aluminum, copper, lead, and nickel.

[18] This lag of newspaper advertising behind general business activity in the recovery phase was a characteristic commented on by C. V. Kinter, "Cyclical Influences on Newspaper Advertising," *Am. Jour. Econ. Soc.*, Oct. 1947, VII, 88.

[19] This and the following paragraph are a summary of material from the Canadian Dominion Bureau of Statistics reports on various phases of the mining industry; the *Canada Year Book* annual issues; reports by the provincial Bureau of Mines in Ontario and Quebec; annual reports of the leading Canadian mining corporations; the annual issues of *The Mineral Industry*, edited by G. A Roush (New York); and contemporary reports in the *Financial Post*, *Monetary Times*, *Northern Miner*, and *Economist*. The table is based on data in the *Trade of Canada*.

The wheat areas continued to remain depressed as prices remained low and large stocks accumulated, both in Canada and abroad. Intervention by the Dominion government, which had started in 1930, was not sufficiently strong to offset the world-wide depression in the grain trade. Throughout the 'thirties the Canadian Wheat Board dominated the movement of Canadian wheat, selling off stocks gradually, particularly in 1935-1937, as wheat prices recovered.[20]

In a pattern strikingly similar to that before the 1929 turning point, the Canadian recovery ceased before the American cycle reached its peak. Once again there were specific difficulties within the newsprint and wheat sectors that accounted for the turning point within Canada. Canadian wheat and paper indices started to falter several months before the 1937 drop in the United States. The recovery in Great Britain showed signs of hesitation in the later half of 1936, thus ending the upward movement of Canadian exports to that country. Wheat and wheat flour exports were particularly affected.

Meanwhile, in the United States, perhaps as an advance sign of the recession, newspaper advertising ceased to gain at the beginning of 1937. American newsprint production also stopped increasing. Hence, by the early spring of that year, Canadian wood pulp exports to the United States were losing momentum, as had also occurred eight years before.

At the same time, costs in Canada, as well as in the United States, were rising rapidly, tending to make new investment less profitable. The price index for 30 Canadian industrial materials rose 25 per cent from October 1936 to March 1937, more than in the preceding three and a half years. Wholesale prices rose 12 per cent from May 1936 to July 1937, or as much as in the preceding three years. Comparison of raw materials' and manufactured goods' prices is made in Table II.

In general, it can be said that in 1936-1937 raw material prices (*i.e.*, costs) were rising faster than manufactured goods' prices (*i.e.*, selling prices), thus putting pressure on per-unit margins. Wage rates, too, were rising, the 1936 to 1937 increase of 7.4 per cent exceeding that of the entire preceding three-year period (5.8 per cent).

IV. *The 1937-1938 Recession and Recovery*

These various difficulties within the Canadian economy made it vulnerable to the 1937 recession in the United States. However, unlike the situation in 1929, Canada's other foreign markets continued to provide support, as a result of the increasing rearmament programs. For

[20] For a discussion of the wheat situation, *cf.* contemporary accounts in *Wheat Studies* and the *Economist*.

TABLE II.—CANADIAN PRICE INDICES
(1926=100)

	1933 Low	Start of 1936 Rise[a]	Percentage Rise, 1933 to 1936	1937 High	Percentage Rise, 1936 to 1937
Field Origin					
Raw materials	34.5[b]	55.0	59.4	91.0	65.5
Manufactured	65.2	70.3	7.8	87.0	23.8
Animal Products					
Raw materials	55.0	70.1	27.5	84.9	21.1
Manufactured	58.8	70.0	19.0	79.0	12.9
Forest Products					
Raw materials	64.4	73.6	14.3	98.0	33.2
Manufactured	55.9	55.9	0.0	70.2[c]	25.6

Raw materials	74.8	78.8	5.3	88.8	12.7
Manufactured	83.4	84.8	1.7	93.1	9.8

[a] For more than a year, following the 1933–1934 upswing, wholesale prices had remained fairly stable. These eight groups then resumed their rise at varying months in 1936, the particular month for the start having been selected after inspection of the charted time series.

[b] December 1932.

[c] January 1938.

For descriptions of the indices, see the Dominion Bureau of Statistics' annual series, *Prices and Price Indexes*.

example, in Great Britain, despite the recession there, construction and heavy goods industries held up, thus sustaining the demand for Canadian nonferrous metals.[21] As a result, the decline in the level of economic activity within Canada was less, proportionately, than that in the United States. Although the latter's exports were also aided by the overseas rearmament outlays, the lesser rôle played by foreign trade made the stimulating effects much less intense.

The support provided by the Canadian mining industry made it, in the words of an *Economist* correspondent, "one of the chief buttresses of Canada's economy."[22] The value of its output was down less than 5 per cent from 1937 to 1938, while employment actually rose. Of the main minerals, physical output rose from 1937 to 1938 for gold, copper, lead, zinc, petroleum, and natural gas. Silver, salt, and gypsum decreased less than 5 per cent and only asbestos showed a decrease larger than 10 per cent.

The lesser impact on Canada is shown by the production indices in Table III.

In contrast to the preceding (1929-1933) depression, recovery came

[21] J. A. Brown, "The 1937 Recession in England," *Harvard Bus. Rev.*, 2, winter 1940, XVIII, 254.

[22] July 16, 1938, p. 120.

quite quickly. The American pump-priming policy plus European rearmament soon brought both Canada and the United States into the upward phase of the cycle for the remainder of the period before the outbreak of the war. Many British armanent orders were placed with Canadian firms, particularly in the iron and steel industry, including contracts for the construction of new plant facilities.

With the revival of U.S. industrial output and incomes, Canadian exports to the United States picked up, increasing almost 70 per cent from February to November 1938. Exports to Great Britain almost

TABLE III.—CANADIAN AND UNITED STATES PRODUCTION INDICES
(1935–1939 = 100)

	1937 High	1937–1938 Low	Percentage Drop
Manufacturing production			
Canada	118.4	89.5	−24.4
U.S.	123	79	−35.8
Producers' goods—Canada	115.2	94.8	−17.7
Durable manufactures—U.S.[a]	135	66	−51.1
Machinery—U.S.	134	75	−44.0
Consumers' goods—Canada	114.9	91.4	−20.5
Non-durable goods—U.S.	114	88	−22.8

[a] Includes transportation—automobiles, aircraft, railroad cars, etc.

doubled from April to October 1938. The main nonferrous metals—aluminum, copper, lead, and nickel—now accounted for 15 to 20 per cent of total Canadian exports, double the proportion of the pre-1930 years. Wheat and wheat flour exports recovered, too, both because of the general rise in incomes throughout the world, and because of stockpiling programs in anticipation of war.

Hence, with the European armament programs sustaining exports to that area, and with the additional support afforded by the revival in the United States, Canadian indices turned up, soon recovering most of the ground lost in 1937-1938. From the 1938 low to the highest succeeding month before the outbreak of World War II, Canadian manufacturing output rose 24 per cent; mining output rose 35 per cent, to a level 10 per cent above the 1937 high. The producers' goods industries also stepped up production sharply, with an increase of 22 per cent, to equal the 1937 high, partly as a result of the tripling of new private construction contracts awarded. Although a level of full employment was not attained until the wartime period—even the 1937 high had not reached that point—it was still a decidedly upward movement. With the outbreak of hostilities, of course, the indices were to register much greater gains.

V. *Summary and Conclusion*

One factor which should be stressed is the importance of events and tendencies which were of particular concern to the Canadians, or to some one Canadian activity, yet which, in themselves, were not major events of international significance. The pressure by American purchasers of newsprint for price cuts in 1928, on the surface, was a purely local problem, hardly important enough to count, as a cycle determinant. Yet, because of its occurrence at a time when the Canadian newsprint industry had expanded so greatly as to put itself in a vulnerable position, the American publishers were able to seize the opportunity to "break" the existing schedule of prices. This, in turn, by causing an important segment of the Canadian economy to suffer, helped to bring about the earlier turn in the Canadian cycle in 1929.

In fact, one is struck by the importance of the economic relationships between particular segments of the economy, especially for the explanation of the upper turning point. It has usually been this intertwining of relationships that has served to explain the specific movements analyzed. Thus in 1929 it was not the succession of events leading up to the world-wide collapse in the autumn, but the developments centering around the expected poor wheat harvest within Canada—and the resulting wheat holdback—that explain the drop in Canadian exports and the accompanying adverse balance and foreign exchange difficulties. True, Canada was also caught up in the same forces that were working on the other countries of the world, but these were not the dominating factors directly determining the Canadian turning point. We thus come back to what have been termed "real causes," such as D. H. Robertson offered as possible explanations of the cycle—changes in overseas demand as a result of the vagaries of harvests, war, fashion, etc.[23] The unity of international markets, the interconnections as a result of international specialization, all the innumerable ties that connect the supplier with his customers, become the logical answer for the analyst seeking to determine the cause and effect of movements in the level of activity of related trades.

To a certain extent this relative independence from world cyclical events had an element of the fortuitous. The fortunate possession of undeveloped mineral resources which came within the range of efficient operating costs at just the appropriate time helped make possible the beginning of the upswing in 1932-1933. What would have happened to the Canadian economy if its vast reserves of unmined gold had not existed, as well as the accompanying expansion of the base metals, is

[23] *Cf. e.g., A Study of Industrial Fluctuation* (London, 1915), especially pp. 71-73, 148-49, 181-82.

not difficult to imagine. The wheat economy was depressed; the newsprint industry was plagued with low prices, overproduction, and widespread bankruptcies; neither of these could have provided the necessary stimulus. Certainly, Canada was fortunate in possessing these alternative natural resources at just the right stage of development to come into production on a tremendously enlarged scale.

For the analysis of the upswings, it has been the income levels of the main Canadian customers—the United States and Great Britain—rather than price movements that have been important. This was most strikingly illustrated during the 1931-1933 period of currency disturbances, when Canadian exports rose to those countries whose internal activity was improving, even though their currencies had depreciated relative to the Canadian dollar, and exports suffered if the consuming country's activity were decreasing, even though its currency had appreciated in terms of the Canadian dollar.

During the twelve years studied price was of some importance in determining the demand for Canadian products—for example, too high a price for wheat in 1929 resulted in the loss of much of her overseas market. The significance of the influence of price was reduced, however, by the fact that the leading Canadian exports were governed by a demand that was comparatively inelastic; for newsprint, the main destination was the American newspaper industry, where stability of the newsstand price and advertising rates prevented any variation in the cost of newsprint from being reflected in the final price to the reader, thus nullifying any effects through derived demand. Similarly, most of the outlets for Canadian nonferrous metals were also characterized by an inelasticity of demand. Much of this demand, particularly in the late 'thirties, was in the growing rearmament progams; here the volume purchased depended on the size of the country's budgetary appropriation, rather than the price of the materials required. Moreover, since Canada was a low-cost producer of most of these minerals, further reduction of the sales price would not have increased her relative advantage, and thus her share of the market, since she already had a commanding position. As for wheat, other than the importance of the relative price as compared with competing wheats, the inelasticity of demand for such foodstuffs also worked to minimize the influence of price variations.

In brief, Canada was free to depress herself in advance of the world turning point, but she could not recover before her main foreign markets also enjoyed an upswing.

SRAFFA'S *RICARDO*[1]

By GEORGE J. STIGLER*

Ricardo was a fortunate man. He lived in a period—then drawing to a close—when an untutored genius could still remake economic science. He lived in a nation where two great problems, inflation and free trade, gave direction and significance to economics. And now, 130 years after his death, he is as fortunate as ever: he has been befriended by Sraffa—who has been befriended by Dobb.

Keynes told us, in 1933, that Sraffa, "from whom nothing is hid," would give us the full works of Ricardo within the year.[2] The truth of the first part of the statement had as its cost the falsification of the second, and it has been a splendid bargain. For Sraffa's *Ricardo* is a work of rare scholarship. The meticulous care, the constant good sense, and the erudition, make this a permanent model for such work; and the host of new materials seem to suggest that Providence meets half-way the deserving scholar. The Royal Economic Society, his patron, displays its justifiable pride in the outcome of this venture by the excellence of the presentation of the work.

I shall not attempt any general estimate of Ricardo's work. It does not seem called for: these nine volumes often amplify and sometimes modify our understanding of his doctrines, but they do not change it in essentials. This is desirable as well as inevitable: it would be high tragedy if Ricardo had been forced to wait more than a century before revealing his ideas. Moreover, there is little point in the conventional "estimates" of past economists. One can indeed debate the desirability of the influence Ricardo exerted on economics, but his vast influence is undeniable and the debate serves no clear purpose beyond exciting his heirs and intellectual assignees. I doubt whether dead professors should be graded—but for those who must have grades, I think Ricardo's policy recommendations were profoundly good but his theory was not of the highest quality.[3]

Be that as it may, I shall restrict my comments to three subjects: the quality of the edition; Mill's influence on Ricardo; and Ricardo and Malthus on Say's Law.

* The author is professor of economics at Columbia University.

[1] Reflections on *The Works and Correspondence of David Ricardo,* edited by Piero Sraffa with the collaboration of M. H. Dobb, in nine volumes (Cambridge, Eng. and New York, 1952). References to volume and page will be by roman and arabic numbers respectively.

[2] *Essays in Biography* (London, 1933), p. 138.

[3] And T. W. Hutchison flunks him; "Some Questions about Ricardo," *Economica* (1952), XIX, 415-32.

I. *The Quality of the Edition*

Sraffa's edition seems to breathe precision, so it was only with difficulty that I brought myself to test a small portion of it. The test consisted of a comparison of roughly one-tenth of the paragraphs of his text of the *Principles* with the first edition.[4] The impression of precision is well-founded; I found only one large error.[5] Any economist who does not appreciate how extraordinary such accuracy is, should spend an hour or two checking published quotations.

Aside from the introduction to Volume I, Sraffa's editorial prefaces and notes serve an informative, rather than an interpretive, function. This severe self-abnegation was wise: the facts are relatively timeless but even the best analysis of a predecessor will change with the interests and knowledge of the science. The editorial notes are superb. They seem unbelievably omniscient; they are never obtrusive or pedantical; and they maintain unfailing neutrality. Their presence not only clarifies much of Ricardo's work but also provides a vast fund of information on the economics of the period.

Others may be as uncomfortable as I at undiluted praise, and perhaps one should criticize Sraffa for the insertion of an erroneous "not" (VIII, 359) or argue the irrelevance of the splendid tale of Mr. ——— (III, 427 ff.) in order to emphasize more subtly the superlative quality of the scholarship. But usual rules must bow to unusual events: here is a task that need not be performed again.

II. *Mill and Ricardo*

Ricardo's correspondence opens in 1810, a year after he made the public plunge into economics, and closes with the sad letters of his friends describing his death in 1823. In the former year he was 38, Malthus was 44, Say was 43, James Mill was 37, McCulloch was 31, and John Mill, still busy with Greek, was 4.

In the few letters between Say and Ricardo, the Frenchman seems soft and muddled in comparison with the tough-minded Ricardo. Say's approach was fundamentally much more modern than that of his English contemporaries, but he lacked the intellectual power to develop it satisfactorily. The correspondence makes McCulloch out a less servile and uncritical disciple than legend would have him; for example, he sturdily opposed, although not on the best grounds, Ricardo's mistaken theory of the effects of machinery (fixed capital) on wages (VIII, 381 ff.). The many letters to Trower, an intelligent stockbroker friend of Ricardo's, provide exercise in exposition to Ricardo and relaxation to the reader. Trower was an amiable man, and one imagines with compassion his reception when he unsuccessfully tried to tell a rural audience,

[4] Sraffa will be pleased to learn that his conjecture as to how two Chapter VIII's appeared in the first edition is verified (I, xxviii). The copy in the Columbia library has an uncorrected page 220, which continues with the opening passages of the second Chapter VIII; the corrected pages 219-22 were bound in the index.

[5] Sraffa fails to report, I, 149, line 24, that "they" was "we" in the first edition.

at a time when the price of corn was catastrophically low, that its troubles were augmented by decreases in agricultural taxes (IX, 165n.).

The major interest of the correspondence lies in the letters of Mill and Malthus, most of which have not previously been published. The Mill letters illuminate his rôle in directing Ricardo's career—they are unimportant on matters of economics since Mill was inactive in economics during most of the period. The Malthus letters present the debate over a large number of scientific differences that separated the two leading English economists of the period. We begin with Mill.

Mill had come to London in 1802 to make his way as a writer—a move that surely improved the Scotch Presbytery as well as the literary journals of London.

> The extent of his acquired knowledge and original thinking, when he left Scotland at the age of twenty-nine, will be judged by what he was able to do in the next few years. He kept back from the aspiring Scotchman's venture upon London, until he had attained an unusual maturity of intellectual power; while possessed of good ballast in the moral part. Moreover, we are to conceive of him as a youth of great bodily charms. One of my lady informants spoke of him with a quite rapturous admiration of his beauty. His figure and proportions were fine; the short breeches of the time showed a leg of perfect form. His features beamed with expression. Nothing was wanting that could prepossess people's favourable regards.[6]

Already in 1804 he wrote a first, very poor pamphlet on foreign trade,[7] and in 1808 a second, very able pamphlet, *Commerce Defended,* so he was already an economist of sorts when his acquaintance with Ricardo began.

Ricardo had a great respect for Mill, and so should we. Mill had an integrity, a strength of purpose, and a public spiritness that ordinary men can only admire. He married in 1805, apparently not very wisely, and the twenty greatest years of his professional life were devoted to earning a livelihood as a journalist and editor. He lived partly on the bounty of Bentham, a crotchety landlord. Yet over these years he found the time and energy to educate his oldest son in a manner unparalleled in written history, and to write his famous *History of British India.*

Mill was a man of considerable logical power, wanting only that mysterious gift of insight to achieve greatness. His will could shatter Sheffield steel, and his opinions were no softer;—here is an example:

> We are as little able to humble Bonaparte, as Bonaparte is to humble us. There is hardly any human event that is less within the reach of chance than the humiliation of Bonaparte by the prolongation of our hostilities. This is a truth in which all men appear at last to be agreed; it is so evident that it seems to defy objection.[8]

[6] A. Bain, *James Mill* (London, 1882), p. 35.

[7] *An Essay on the Impolicy of a Bounty on the Exportation of Grain.*

[8] *Commerce Defended* (London, 1808), p. 128.

The portrait of the cold machine of a man drawn in his son's *Autobiography* is no doubt a fair-minded picture, but reflects also the serious human shortcomings of the artist. The letters show a little more of the human being, although the gallantries to Ricardo's womenfolk are most ponderous. In plain fact, I disagree with Bain: something was lacking in Mill to prepossess our favorable regards. But let us get on to Ricardo.

In the late summer of 1815, Mill began to press for a treatise. Ricardo was settled on his estate, Gatcomb Park, and now "sufficiently rich to satisfy all my desires, and the reasonable desires of all those about me" (VI, 262), when Mill's campaign began.

> When I am satisfied, however, that you can not only acquire that reputation [for talents, and profound knowledge of an important subject], but that you can very greatly improve a science on which the progress of human happiness to a singular degree depends; in fact that you can improve so important a science far more than any other man who is devoting his attention to it, or likely to do so, for Lord knows how many years—my friendship for you, for mankind, and for science, all prompt me to give you no rest, till you are plunged over head and ears in political economy.
>
> I have other projects upon you, however, besides. You now can have no excuse for not going into parliament. . . . (VI, 252.)

Within a week Ricardo agreed to make the attempt:

> Whether it be art in you, knowing how effectual the desire of distinction is in calling forth exertion and talent, to persuade me that I have certain capabilities, in order by the reward which you display in such glowing colours, and to which I am feelingly alive, to stimulate me to exertion and put my power to the test,—or whether you are really satisfied that I have those capabilities I am not quite sure,—but of this I am certain that if the latter is your opinion you are completely deceived. . . . The experiment shall however be tried,—I will devote as much time as I can to think and write on my favorite subject. . . . (VI, 262-63.)

The letters now unfold the picture of a strict but kindly master dealing with a brilliant but unconfident and procrastinating pupil. There are detailed instructions on the high art of composition (VI, 329, 339),—and even on the way to organize one's time (VI, 340). Ricardo periodically despairs, as in a letter to Trower: "Thus you see that I have no other encouragement to pursue the study of Political Economy than the pleasure which the study itself affords me, for never shall I be so fortunate however correct my opinions may become as to produce a work which shall procure me fame and distinction" (VI, 315; also VII, 54, 89). But the taskmaster just as often revives confidence: "For as you are already the best *thinker* on political economy, I am resolved you shall also be the best writer" (VI, 340).

By the fall of 1816 Mill is receiving portions of the manuscript, and his reaction could not fail to encourage any author:

> My opinion may be given in very few words; for I think you have made

> out all your points. There is not a single proposition the proof of which I think is not irresistible. . . .
>
> You have, therefore, made great progress toward the production of a most admirable book. The style also, is really excellent. . . . And easy then for you to put the last hand to a work which will gain you immortal honour (VII, 98-99).

Ricardo expresses his indebtedness in generous terms:

> How very encouraging your letter is! . . . If I am successful in my undertaking it will be to you mainly that my success will be owing, for without your encouragement I do not think that I should have proceeded, and it is to you that I look for assistance of the utmost importance to me—the arranging the different parts, and curtailing what may be superfluous (VII, 100-01).

In the spring of 1817 the *Principles* appeared, but Ricardo was given no rest. He must have shivered at Mill's wish to have a cottage within a couple of miles of Gatcomb Park: "how I would keep you to it!" (VII, 184). Ricardo again hesitates at Mill's bold plans:

> In the first place I am not very persevering, unless the object for which I work is steadily before my eyes.—I have all the disadvantages too of a neglected education, which it is now in vain to seek to repair. It would be wise in me to stop where I am and not like a desperate gamester venture my gains to the fearful odds to which they are exposed. My mind often misgives me about the Parliamentary scheme, and I think if you knew me as well as I know myself you would advise me against it (VII, 190).

Such excuses were to Mill mere literary lace:

> Which of our *educated* sparks has written such a book as yours? (VII, 196).
>
> You are now, beyond all dispute at the head of Political Economy. Does not that gratify your ambition? And who prophesied all this? Tell me that! And scolded you on, coward that you are? Tell me that! (VIII, 10).

And so, in the fall of 1818 the seat in Parliament is arranged, and Ricardo is instructed to write political discourses as practice for his rôle of legislator.

Should we take these letters at face value and credit Mill with the existence of Ricardo's treatise? I do not know. We must recall that Ricardo wrote the two pamphlets on the bullion controversy and the *Essay* (1815) without apparent intervention by Mill, and the *Proposal* (1816) is due chiefly to Pascoe Grenfell's solicitation. Interest, leisure, and ambition supported the writing of the *Principles*. Nor is there any evidence that intellectual humility was an obstacle to publication for Ricardo. He never deferred to the authority of Malthus, Say, or even Smith; it is always his literary accomplishments, and never his beliefs, for which he apologizes (*e.g.*, VII, 140). The apologies were justified, and a comparison of the early pamphlets with the *Principles* reveals precious little progress in this respect for which Mill might claim credit. Perhaps Ricardo had a phobia on literary composition

that it took a Mill to overcome, but perhaps also Mill, with all his fussing and prodding, merely hastened the work.

I shall not follow any farther the schemes of the Scotch impresario, but before we leave him, let us hear Ricardo's response to still another plan:

> This scheme would not contribute to my happiness. You are mistaken in supposing that because I consider life on the whole as not a very desirable thing to retain after 60, that therefore I am discontented with my situation, or have not objects of immediate interest to employ me. The contrary is the case—I am very comfortable, and am never in want of objects of interest and amusement. I am led to set a light value on life when I consider the many accidents and privations to which we are liable. . . . No one bears these serious deprivations with a better temper than myself, yet I cannot help anticipating from certain notices which I sometimes think I have, that many more await me. I have not I assure you seriously quarreled with life,—I am on very good terms with it, and mean while I have it to make the best of it, but my observation on the loss of esteem and interest which old people generally sustain from their young relatives . . . convinces me that general happiness would be best promoted if death visited us on average at an earlier period than he now does (VIII, 253).

Ricardo got both wishes: he did not become a director of the East India Company; and within three years he was dead.

III. *Ricardo and Malthus: Say's Law*

Malthus was already the celebrated author of the *Essay on Population* and the only professor of political economy in England when his friendship with Ricardo began. They must have been uncommonly fond of each other to persist in an intimacy despite great scientific and intellectual differences and despite their rivalry for the dominance of English economics.

Malthus had one wondrous gift, the intuition to bring to an explicit level deep problems of economic life. His claims are vast: he was an independent discoverer of the "principle" of population; of the theory of rent; and of the fact of a relationship between saving and the level of economic activity. And he had one great weakness—he could not reason well. He could not construct a theory that was consistent with either itself or the facts of the world.

The correspondence should perhaps give us occasion for despair. The leaders of the science, honorable men seeking earnestly for truth, could hardly ever resolve a difference after the most protracted exchanges, and the pages on pages of dreary repetition of arguments tells us again how odd an instrument the human mind is. It would be admirable training, and in more than economics, for our graduate students to write analyses of one of these disputes.

We could follow their early exchanges over the theory of profits or their final dispute over the measure of value, but most readers will probably prefer a discussion of the controversy over what is called Say's Law. This choice is commended by its impartiality, for neither man held an enviable position.

J. B. Say first presented his law of *débouchés,* without fanfare or details,

in 1803. Each individual specializes in production, and the surplus of his product over his needs is exchanged for the surplus products of others.

> This shows, I believe that it is not so much the abundance of money, but rather the abundance of other commodities in general, that facilitates sales. . . .
>
> In this double exchange, money fills only a transitory function. . . . As a result, when a nation has too much of one kind of product, the way to dispose of it is to produce another kind.[9] [my translation]

Without elaboration or application this theory could mean little or much; a theory draws much of its content from its enemies.

Mill presented a similar theory in *Commerce Defended;* it is uncertain whether he was an independent discoverer.[10] One may say that if Say invented the weapon, Mill was the first to slay a duck. The duck was William Spence, a physiocrat, who argued, *inter alia,* that the expenditure of landlords on luxuries was essential to maintain the markets for agricultural produce (and inferentially, all markets). Mill refuted this argument by showing that savings which were invested would continue to provide a demand for the services of the "sterile" groups.[11]

Mill went on to dispute a notion of the *Economistes* that "there is only . . . a market for a given quantity of commodities, and if you increase the supply beyond that quantity you will be unable to dispose of the surplus."[12] Mill was led to state the law of markets:

> But if a nation's power of purchasing is exactly measured by its annual produce, as it undoubtedly is; the more you increase the annual produce, the more by that very act you extend the national market, the power of purchasing and the actual purchases of the nation. Whatever be the additional quantity of goods therefore which is at any time created in any country, an additional power of purchasing, exactly equivalent, is at the same instant created; so that a nation can never be naturally overstocked either with capital or with commodities; . . .[13]

Mill's statement was different from Say's in one respect: he explicitly introduced the condition that the composition of output be adapted to the tastes of consumers and investors.[14]

[9] *Traité d'Économie Politique,* 1st ed. (Paris, 1803), I, 153, 154; see also II, 361-63.

[10] He made no claims of originality and he was already acquainted with Say's book (see *Commerce Defended* [London, 1808], p. 76 n.), but also he did not attribute the doctrine to Say.

[11] *Ibid.,* pp. 68ff. Mill argued parenthetically that the savings would be spent more rapidly than the portion of income reserved for consumption; *ibid.,* pp. 76-77.

[12] *Ibid.,* p. 80.

[13] *Ibid.,* p. 81.

[14] "All that here can ever be requisite is that the goods should be adapted to one another; that is to say, that every man who has goods to dispose of should always find all those different sorts of goods with which he wishes to supply himself in return." *Ibid.,* pp. 82-83, also p. 85.

Ricardo became acquainted with Mill through this pamphlet,[15] and he embraced Mill's version without reservation. In fact Ricardo went considerably beyond the law in his denial that the quantity of money could have any influence on real output. He was called upon in late 1810 to referee for possible publication a manuscript of Bentham's. Bentham made much of the point that if an increase in the stock of money were given to the productive classes (entrepreneurs), they would bid up prices (thus imposing forced savings on fixed income groups) but the amount of investment would be increased. Ricardo commented:

> That money is the causes [sic] of riches has been supported throughout the work and has in my view entirely spoiled it (III, 318).
>
> An augmentation of money in all cases operates to the disadvantage of some and the advantage of others,—it will neither accelerate nor retard the growth of real riches (III, 325).

Ricardo's objections were fundamentally empirical: the lag of wages behind prices would be of only "momentary duration" (III, 319); and it was "mere speculation" whether entrepreneurs would save more of a given real income than the fixed income recipients (III, 333; also VI, 15-16). His empirical judgments, however, were excessively dogmatic, and he treated his conclusion as if it were as certain as an analytical theorem. His objections considerably delayed the publication of Bentham's essay.[16]

Within a few months Ricardo made this position public, in the *High Price of Bullion* (III, 120-23), and at the same time disputed the possibility of a general glut. Malthus, in reviewing various pamphlets (including both of Ricardo's) on the bullion controversy, dissented from Ricardo's argument that premiums on foreign currencies are due only to overissue of currency. If there is a crop failure, the exchange might move adversely to a country when it imported corn because "the prices of commodities are liable to general depressions from a glut in the market."[17] Ricardo restated Mill's law, with characteristic vigor:

> No mistake can be greater than to suppose *that a nation can ever be without wants for commodities of some sort*. It may possess too much of one or more commodities for which it may not find a market at home . . . but no country ever possessed a general glut of all commodities. It is evidently impossible. If a country possesses every thing necessary for the maintenance and comfort of man, and these articles be divided in the proportions in which they are usually consumed, they are sure, however abundant, to find a market to take them off (III, 108).

Malthus soon sought out Ricardo, and henceforth the controversy continued in their correspondence.

[15] J. S. Mill, *Principles of Political Economy*, Ashley ed. (London, 1929), p. 563.

[16] It is now to appear in Volume III of Stark's edition of *Bentham's Economic Writings*.

[17] "Publications on the Depreciation of Paper Currency," *Edinburgh Review*, No. 34 (Feb. 1811), p. 345.

During 1814 and 1815, when Malthus and Ricardo were publishing highly incompatible pamphlets on the corn laws, the former expressed more openly his scepticism of Mill's law.

> In short I by no means think that the power to purchase necessarily involves a proportionate will to purchase; and I cannot agree with Mr. Mill in an ingenious position which he lays down in his answer to Mr. Spence, that in reference to a nation, supply can never exceed demand. A nation must certainly have the power of purchasing all that it produces, but I can easily conceive it not to have the will. . . . It is not merely the proportion of commodities to each other but their proportion to the wants and tastes of mankind that determines prices (VI, 132).

Ricardo would not admit the possibility of a lack of desire:

> I go much further than you in ascribing effects to the wants and tastes of mankind,—I believe them to be unlimited. Give men but the means of purchasing and their wants are insatiable. Mr. Mill's theory is built on this assumption. It does not attempt to say what the proportions will be to one another, of the commodities which will be produced in consequence of the accumulation of capital, but presumes that those commodities only will be produced which will be suited to the wants and tastes of mankind, because none other will be demanded (VI, 148).

Malthus did not deny categorically the insatiability of human wants, nor has any married economist since his time, but he repeatedly argued that a taste for luxuries developed only slowly (VI, 155). It is difficult to see why a lack of wants would lead to a glut of markets, however, since men so constituted would simply not produce in excess of their desires and any surplus of productive capacity would be devoted to indolence—the classical economists' word for leisure.[18]

J. B. Say dealt more elaborately, but not much more precisely, with the law of markets in the second edition of the *Traité* (1814).[19] His formulation was essentially a truism: Assume that money receipts are always promptly spent; then an offer of one commodity is always an implicit demand for another.[20] This truism has properly been labeled Say's Identity. Say goes beyond this truism, or contradicts it, when he asserts that some commodities

[18] We find Malthus seriously confused on the nature of income. He insisted that the "true question" was whether prices would fall if output increased greatly, income remaining constant, and would not accept Ricardo's argument that income inevitably rose under this assumption (VI, 142, 148, 155-156).

[19] *Traité d'Économie Politique*, 2d ed. (Paris, 1814), Vol. I, Ch. 15.

[20] "Il est bon de remarquer qu'un produit créé offre, *dès cet instant*, un débouché à d'autres produits pour tout le montant de sa valeur; car tout produit n'est créé que pour être consommé, soit reproductivement, soit improductivement, et même pour être consommé le plutôt possible, puisque toute valeur qui attend, fait perdre à celui qui en est actuellement le possesseur, l'intérêt de cette attente; le marchand a soin de ne pas avoir des marchandises qui doivent rester en magasin, et le consommateur a soin de ne pas en acheter très-long-temps avant le moment d'en faire usage. Un produit est donc toujours, autant que chacun peut, destiné à la plus prompte consommation. Du moment qu'il existe, il cherche donc un autre produit avec lequel il puisse s'échanger" (*Ibid.*, pp. 147-48).

lack a market because insufficient amounts of other commodities are being produced,[21] but he does not introduce any conditions (such as rigid prices) which would bring such a disequilibrium about.

When Ricardo came to write the *Principles,* he developed the law of markets along Mill's line (I, 289ff). He too had each recipient of money spend it promptly; "he would not lock it up in a chest" (I, 291). But he asserted that no matter how large the accumulation of capital, all commodities could be sold for prices equal to their costs of production provided the commodities suited consumers' tastes:

> There cannot, then, be accumulated in a country any amount of capital which cannot be employed productively, until wages rise so high in consequence of the rise of necessaries, and so little consequently remains for the profits of stock, that the motive for accumulation ceases (I, 290).
>
> Too much of a particular commodity may be produced, of which there may be such a glut in the market, as not to repay the capital expended on it; but this cannot be the case with respect to all commodities; . . . (I, 292).
>
> It follows then from these admissions that there is no limit to demand—no limit to the employment of capital while it yields any profit, . . . (I, 296).

In this form the law of markets is no longer a truism, it is the proposition that general equilibrium of the economy, with prices equal to costs (including "profits"), is compatible with any level of real income. It would be more appropriate to call this the Mill-Ricardo Law than Say's Law.

Ricardo marred this theory by making a concession to Malthus:

> There is only one case, and that will be temporary, in which the accumulation of capital with a low price of food may be attended with a fall of profits; and that is, when the funds for the maintenance of labour increase much more rapidly than population;—wages will then be high, and profits low (I, 292-93).

This is consistent with his theory, but he continues:

> If every man were to forego the use of luxuries, and be intent only on accumulation, a quantity of necessaries might be produced, for which there could not be any immediate consumption. Of commodities so limited in number, there might undoubtedly be a universal glut, and consequently there might neither be demand for an additional quantity of such commodities, nor profits on the employment of more capital. If men ceased to consume, they would cease to produce (I, 293).

The concession is mistaken: if all luxuries were abandoned for savings, there would be no piling up of necessaries, and for that matter their quantity might not increase at all. The output of fixed capital would rise as that of luxuries fell.

We should note that Ricardo did not interpret his law of markets as exclud-

[21] *Ibid.*, pp. 148-50.

ing the possibility of general commercial distress. On the contrary, he devoted a chapter (19) to Sudden Changes in the Channels of Trade, which he believed could for a time occasion widespread distress. Beginning in 1815, however, he made a series of predictions that prosperity would soon come to England (*e.g.*, VI, 232, 345; VII, 49, 170-71; etc.). The prediction was continuously wrong, and it was no compliment to his intelligence that after 1820 he blamed the distress on the abundance of harvests.

The controversy reached a climax with the publication of Malthus' *Principles* (1820). Malthus' theory has been praised lavishly in recent times, but it does not contain any germs of a theory of underemployment equilibrium. We may state with confidence that it does not turn on hoarding: "No political economist of the present day can by saving mean mere hoarding; . . ."[22] In fact his theory is entirely nonmonetary in nature, and the prominence given to a footnote on the importance of money is hard to explain and impossible to justify.[23]

The fundamental argument is expressed as follows:

> It is undoubtedly possible by parsimony to devote at once a much larger share than usual of the produce of any country to the maintenance of productive labour; and it is quite true that the labourers so employed are consumers as well as unproductive labourers; and as far as the labourers are concerned, there would be no diminution of consumption or demand. But it has already been shewn that the consumption and demand occasioned by the persons employed in productive labour can never alone furnish a motive to accumulation and employment of capital; and with regard to the capitalists themselves, together with the landlords and other rich persons, they have, by the supposition, agreed to be parsimonious, and by depriving themselves of their usual conveniences and luxuries to save from their revenue and add to their capital. Under these circumstances, I would ask, how is it possible to suppose that the increased quantity of commodities, obtained by the increased number of productive laborers, should find purchasers, without such a fall of price as would probably sink their value below the costs of production, or, at least, very greatly diminish both the power and the will to save.[24]

This theory is wrong. An amount of savings is matched by an amount of capital goods, and the act of saving need exert no downward pressure on the

[22] *Principles of Political Economy* (London, 1820), p. 32.

[23] The footnote, which has no relevance to the text, is:

Theoretical writers in Political Economy, from the fear of appearing to attach too much importance to money, have perhaps been too apt to throw it out of their consideration in their reasonings. It is an abstract truth that we want commodities, not money. But, in reality, no commodity for which it is possible to sell our goods at once, can be an adequate substitute for a circulating medium, and enable us in the same manner to provide for children, to purchase an estate, or to command labour and provisions a year or two hence. A circulating medium is absolutely necessary to any considerable saving; and even the manufacturer would get on but slowly, if he were obliged to accumulate in kind all the wages of his workmen. . . . (*Ibid.*, pp. 361-62 n.).

[24] *Ibid.*, pp. 352-53 (also II, 301-03).

prices of consumption goods. Malthus' error arises from his assumption that capital formation takes the form only of accumulating the necessaries of labor, *i.e.*, all capital is circulating capital.

Ricardo wrote a critique of the *Principles* at McCulloch's request, and a fair share of it is devoted to the theory of gluts. Ricardo accepts Malthus' theory, with one important correction. If saving leads to a large accumulation of necessaries (Ricardo also improperly identifies capital with circulating capital), which is not accompanied by a corresponding increase of population, wages will rise; Malthus on the contrary argues that wages will fall.[25]

> But if a great quantity of commodities will command little labour, every labourer will have the power to consume a great quantity of commodities. The will to consume exists wherever the power to consume is. Mr. Malthus proves that this power is not annihilated but is transferred to the labourer. We agree with him and say wherever the power and will to consume exists there will necessarily be demand (II, 311).

Malthus fends this attack by introducing rigidity of wages: "We know from repeated experience that the money price of labour never falls till many workmen have been for some time out of work" (IX, 20). Ricardo finds this argument without merit: "I know no such thing, and if wages were previously high, I can see no reason whatever why they should not fall before many labourers are thrown out of work" (IX, 25). Malthus did not pursue this argument.

It is a question of words whether rapid capital accumulation, leading to high wages and low profits, should be said to create a glut; certainly all markets still may be in competitive equilibrium, and no commodity need sell for less than cost. Whatever its name, Ricardo admits that this situation may lead to a cessation of capital accumulation, until the increase of population lowers wages and restores profits.

> Mr. Malthus asks "how is it possible to suppose that the increased quantity of commodities, obtained by the increased number of productive labourers should find purchasers, without such a fall of price as would probably sink their value below the cost of production, or, at least, very greatly diminish both the power and the will to save? [''] To which I answer that the power and the will to save will be very greatly diminished, for that must depend upon the share of the produce allotted to the farmer or manufacturer. But with respect to the other question where would the commodities find purchasers? If they were suited to the wants of those who would have the power to purchase them, they could not fail to find purchasers, and that without any fall of price (II, 303-04).

> What I wish to impress on the readers mind is that it is at all times the bad adaptation of commodities produced to the wants of mankind which is the specific evil, and not the abundance of commodities (II, 306).

This concession pertains only to rapid *changes* in the amount of savings, and is independent of the level of savings.

[25] *Ibid.*, p. 362 (also II, 316-17).

Say made a more prolix refutation in his *Letters to Malthus*.[26] Say's letters have considerable merit, and in particular they contain a remarkable sketch of the circular flow in an enterprise economy. But they emphasize Say's lack of precision, and at one point he makes a fatal admission:

> Mr. Ricardo claims that, in spite of taxes and other fetters, the extent of industry is always as great as that of the capital employed, and that all savings are always employed because the capitalists do not wish to lose the interest. On the contrary, there are considerable savings that are not invested when it is difficult to find a use for them, or which, once invested, are dissipated in a mistaken undertaking.[27] [my translation]

Malthus claimed that this concession was "all that I contend for" (VIII, 260), which is not true because Malthus did not make hoarding the basis of his argument. But he was right in saying that Say did not understand his peculiar position: "This important distinction however Say does not make for me, but runs off into an 'Eh! Monsieur!' " (VIII, 261). Ricardo also felt that the *Lettres* "are not very well done" (VIII, 276).

Ricardo once more came against a critic of the Mill-Ricardo theory when he wrote a commentary (IV, 325-56) on William Blake's *Observations on the Effects Produced by the Expenditure of Government* (London, 1823), to which Blake wrote a rejoinder. Blake attributed the postwar distress to "the transition from an immense, unremitting, protracted, effectual demand, for almost every article of consumption, to a comparative cessation of that demand."[28]

> I believe there are at all times some portions of capital devoted to undertakings that yield very slow returns and slender profits, and some portions lying wholly dormant in the form of goods, for which there is not sufficient demand. I believe, too, that when capital accumulates rapidly from savings, it is not always practicable to find new modes of employing it. Now, if these dormant portions and savings could be transferred into the hands of government in exchange for its annuities, they would become sources of new demand, without encroaching upon the existing capital.[29]

Blake's discussion contained ample confusion and lacunae, but Ricardo's rejoinder was not impressive: his mind was closed on the subject, and he insisted on postulating full employment in dealing with a theory of unemployment (IV, 356).

We have touched on only a small part of the contemporary literature bearing on market gluts, but a review of Ricardo's works is not an appropriate occasion for a full survey. Even this strand of the literature, however, is enough to tell us that the analysis rose above the level of bare truisms and

[26] *Lettres à M. Malthus* (Paris, 1820). There is a grotesque "translation"; *Letters to Malthus*, reprinted (London, 1936).

[27] *Lettres*, p. 101 n.

[28] *Observations*, p. 88.

[29] *Ibid.*, pp. 54-55 (and IV, 340).

blind disregard of commercial fluctuations. The triumph of Ricardo over Malthus cannot be regretted by the modern economist: it is more important that good logic win over bad than that good insight win over poor.

IV. *Conclusion*

One leaves Ricardo with some envy. In his time economics was at least as pleasant a subject as it is today. The basic truths of the science seemed almost within grasp: only a few concepts like the measure of value had still to be tidied up, or so it seemed. The frustratingly complex economy which generations of research have uncovered was still hidden in the future. The truths of economics then led directly to good social policy, which only an unrepresentative, soon to be reformed, Parliament sometimes prevented from being translated into immediate action. The possibility that good economics will not inevitably carry the day in a democracy, of which we are acutely aware, also dwelled in the unpredicted future. A diligent economist, to mention a smaller but not negligible attraction, could read all the worthwhile economics appearing and still have time to do work of his own. Indeed, if he were merely to reside in London, "the place in which we meet a succession of clever men . . . and in which we gain instruction by the active opposition which all our speculations whether right or wrong encounter" (IX, 312), he could exchange opinions with a majority of the world's good economists. But we must be content with our compensations, which include things as precious as greater knowledge and greater humility.

We are still to receive from Sraffa a biography of Ricardo. We shall wait for it with the patience which he munificently rewards.

Biological Analogies in the Theory of the Firm: Comment

Edith Penrose's "Biological Analogies in the Theory of the Firm" appearing in the December, 1952, issue of this *Review* criticises an article of mine appearing in the *Journal of Political Economy* on the ground that it rests on the theory of biological evolution.[1] A brief reply may serve to bring out some points of scientific value.

The presently relevant aspects of my original article can be summarized briefly. Economics predicts the observable effects of change in exogenous and endogenous factors impinging on the operation of the economic system. It analyzes the economic effects of these various factors upon the optimal conditions of firms and other basic units. From these deduced changes in optimal conditions it predicts that the constellation of firms found in a new environment will have characteristics closer to the new optimal conditions than to the old. It does not (or should not) assert that any or all of the firms in the original circumstances will adjust or modify themselves to achieve the conditions which are optimal for the new conditions. What it does (or should) say is that in the new environment the observed characteristics of the population of firms will be found to have changed toward the new optimal conditions. And this will have happened whatever the wisdom, perspicacity, or motivation of the individual firms. Those who like to think that firms are able to make the required adjustments are free to do so; others, among whom the author is to be counted, can be less restrictive in their axioms and still get similar predicted observable circumstances.

These less restrictive axioms do not assert that businessmen try to maximize profits, since, with uncertainty, no definite meaning can be attached to that prescription of behavior. It is true that there is some situation which, if achieved, would, *ex post*, have yielded a larger profit than any other would have. But this situation is unknowable; hence the lack of prescriptive content. But the economist can, from certain generalized production functions and demand functions, infer the directions of changes in the optimal values of the variables of these functions if these values are now to approach the conditions of the new rather than the old optimum. The economist can do this not because he has greater knowledge than the individual firm but because he is analyzing changes in the optimum conditions of generalized functions. The businessman requires much more than this; he needs to know his particular values, not merely the directions of changes between two different optima derived from generalized functions.

The significant point is that the new optimum is approached even in the

[1] Edith T. Penrose, "Biological Analogies in the Theory of the Firm," *Am. Econ. Rev.*, Dec. 1952, XLII, 804-19.

Armen A. Alchian, "Uncertainty, Evolution and Economic Theory," *Jour. Pol. Econ.*, June 1950, LVII, 211-21.

absence of foresighted appropriate adaptive behavior of individual economic units. It can be induced by differential growth, viability, or profit rates in a competitive regime in which (1) realization of profits is a necessary condition for survival, and in which (2) there is a diversity of adjustments manifested in the variety of factor-service input ratios or consumption patterns.

Economic analysis is therefore not merely a theory of the behavior of individuals; it is a theory of the operation of an economic system, and it yields predictions about the effects of certain changes in both endogenous and exogenous factors affecting the economy. To regard it as a theory of individual behavior is fatal.[2]

With this prologue I now turn to Mrs. Penrose who says she is "not so much concerned to present an analytical critique of the theory as to discuss the applicability of the biological analogy and the implications involved in its use."[3] This is a bit puzzling. The theory I presented stands independently of the biological analogy. Criticisms of the latter are irrelevant to the theory. Mrs. Penrose seems, at the same time, not to have noted another distinction —that between (1) the foundations and development of a theory and (2) the methods of exposition and presentation of it. In my original article every reference to the biological analogy was merely expository, designed to clarify the ideas in the theory.[4]

Having said this much, I could stop if Mrs. Penrose had criticized only the analogy, for then her criticisms would have been irrelevant. But some of her criticisms are directed at the theory, and they are incorrect.

Some of her criticisms rest on logical errors.[5] Most of her criticisms rest on

[2] For example, see the prolonged exchange of views on profit maximization and marginalism beginning with R. A. Lester, "Shortcomings of Marginal Analysis for Wage-Employment Problems" (Mar. 1946) and F. Machlup, "Marginal Analysis and Empirical Research" (Sept. 1946) and continuing for three years in this journal. Machlup's defense of profit maximization and marginalism against those who were trying to test axioms rather than theorems would have been airtight if he had (a) defended profit maximization analysis as based on a set of axioms postulating accurate foresight and from which theorems about the operation of the economic system are derived rather than as a theory of individual entrepreneurial behavior, (b) pointed out the difference between testing axioms and testing theorems, and (c) not defended marginalism or profit maximization as a basis for describing individual behavior in the presence of uncertainty.

[3] Penrose, *op. cit.*, p. 811.

[4] Readers of an earlier draft, containing no references to the biological similarity, urged that the analogy be included as helpful to an understanding of the basic approach. My conviction that they were right has been strengthened by Mrs. Penrose, for, paradoxically, she has revealed that the analogy is even better than I had suspected.

[5] For example, she confuses necessary and sufficient conditions in saying that if we "abandon the assumption" that "businessmen . . . strive to make as much [money] as is practicable" and that "if we assume men act randomly, we cannot explain competition, for there is nothing in the reproductive processes of firms that would ensure that more firms would constantly be created than can survive." *Op. cit.*, p. 812. Except for her insisting on the analytical use of the biological analogy such inferences on her part would be unjustified. Conditions for competition in the two areas, biology and economics, need not be the same; and in any event desire to make a profit is not profit maximization and furthermore random behavior was not assumed; I repeatedly stated that it was used as a starting point for the complete exposition. See also p. 815 where "long run" is interpreted as an actually realized situation.

a misconception of what I wrote. In an extremely revealing footnote, she misconstrued the logic of my position, which she restated as follows: "Economists can know the conditions of survival. . . . Therefore economists can know what firms must do to make zero or positive profits. Therefore economists can know how maximum profits can be obtained."[6] Not only do the second and third sentences represent a *non sequitur*, but in addition they exactly reverse my position. Let me explain this by a little analogy(!) A football coach knows that the condition of winning is making more points than his opponent. Does knowing this imply that the coach can know what his team must do in order to win? Does the coach know how this can be done? Defining a desired condition is not the same thing as knowing how to achieve that condition. The confusion between desired conditions and the methods of achieving those conditions is a confusion which I attempted to expose in my original article. Profit maximization purports to be a definition of a situation, not a statement of a method of achieving that condition. That is what Enke meant when he said it was a description, not a prescription.[7] That distinction is fundamental. Ability to prescribe behavior is not necessary—however helpful it is—for the economist to perform as an economist. I started my presentation in the original paper with an extreme model of "random" behavior in order to emphasize that such special knowledge is not necessary. Subsequently, motivated purposive behavior was introduced—without implying profit maximizing because this could not be defined. It was then stated that even with varied motivations the economist had a method for predicting the types of new situations or firms which would have higher probability of survival and thus tend to become the dominant surviving type. It was denied that the economist could predict which particular firms would survive and what adjustments each particular firm ought to make. Thus all of Mrs. Penrose's criticisms on pages 813-15 miss the point.

Finally, she asserts that "the biological framework in which he cast his model has led him to underestimate the significance" of the precise rôle and nature of purposive behavior in the presence of uncertainty and incomplete information.[8] Whether I am right or wrong in my implicit estimation of the significance of certain undefined types of purposive behavior cannot be judged by examining the axioms from which theorems are derived. Only by testing its predictive value by empirical investigation can the theory and its implications about the significance of a particular type of purposive behavior be evaluated properly.

Surely some of her criticisms must hit their target: but this target is one of her own creation—the utilization of strictly analogous reasoning in which the concepts, conditions and interpretations of a theory in one discipline are blindly picked up and applied in another discipline. Neither Enke nor I did that. And there is a grave danger in shooting so many arrows toward this

straw target. Economics may gain much, as it already has, from the concepts and methods of analysis of other disciplines.

Armen A. Alchian*

* The author is associate professor of economics at the University of California, Los Angeles.

Comment

In the interests of brevity, I shall make only one important point by considering Mrs. Penrose's footnote 26. She wonders "why it is reasonable (on grounds other than professional pride) to endow the economist" employing "viability analysis" with the ability to predict the characteristics of surviving firms adopted by the environment, while not crediting the entrepreneur with equal knowledge. Let us consider gas stations, all operating on a 5 cent a gallon retail margin; there is strong price leadership and enforcement by suppliers, so that this margin is not infringed. If this margin were cut to, say 2 cents, the economist, or any other informed person, can predict that in the long run (1) there will be fewer gas stations, (2) gallonages per surviving station will rise, (3) services will be cut, (4) more emphasis will be placed on lubrications, etc., and (5) costs will fall towards 2 cents a gallon. However, no economist, and no one else, can predict which operator on which location with which brand and which employees might, in fact, survive. It is within the wit of man to describe in aggregate terms some of the qualitative characteristics of surviving firms—but not to prescribe quantitatively the measures that will maximize the profits of an individual firm. Professional pride has nothing to do with it.

Rejoinder

In his original article Alchian wrote: "The suggested approach embodies the principles of biological evolution and natural selection. . . ."[1] If this and similar passages were not intended to imply that these "principles" were in fact part of the "foundation," of this theory, I can only plead a (perhaps pardonable) misunderstanding of them. I am happy to accept his assurance that the biological analogy was used merely as an expository device. The criticism nevertheless remains that the biological analogy places the whole problem in a misleading frame of reference. That I say this indicates that the differences between Alchian and myself, as he pointed out, go much deeper than is revealed by my objections to his analogical reasoning.

My original criticism of the "viability" analysis was simply that it gives an inadequate and inconsistent account of the significance of human motivation in economic affairs. (This is precisely the reason, incidentally, why the biological model fitted it so well.) In trying to avoid the difficulties inherent in predicting human behavior in an uncertain world, Alchian has given us a model in

[1] Armen A. Alchian, "Uncertainty, Evolution and Economic Theory," *Jour. Pol. Econ.*, June 1950, LVII, 211 (hereafter cited as Alchian, *JPE*).

economics which, it seems to me, (1) explains very little—certainly much less than the traditional economic theory—and relies on a grossly misleading and unjustifiable assumption about competition;[2] (2) is mistaken as to the appropriate use of the model of the profit-maximizing individual firm in economic analysis;[3] and (3) is inconsistent in its treatment of knowledge as between economists and businessmen.[4]

I. *The Misleading Assumption of Competition*

Alchian claims as a chief merit of his theory that it does not rely on "predictable individual behavior";[5] the results yielded by it "will have happened whatever the wisdom, perspicacity, or motivation of individual firms."[6] He rejects the "restrictive axiom" that businessmen try to maximize profits, and substitutes the even more restrictive "axiom" that there exists competition so intense that firms must conform to "optimum" conditions in order to survive. Enke has pointed out that "If there is no competition, a great many policies—all 'good' but only one 'best'—will permit an isolated monopoly to survive."[7] Clearly this is true whenever there is a large amount of monopoly in any competitive system. Hence it is necessary to assume intense competition in order to conclude, as Alchian does, that "Among all competitors, those whose particular conditions happen to be the most appropriate of those offered to the economic system for testing and adoption will be 'selected' as survivors."[8]

Now I should not object to this aspect of his model if Alchian could show one of the following to be true: (a) that intense competition could reasonably be expected to occur whatever the conscious motivation of individuals; (b) that sufficiently intense competition exists in reality; or (c) that the assumption leads to more useful results than the assumption it displaces. Both (a) and (b) are satisfied by the biological theory of natural selection, but my original criticism was that neither (a) nor (b) is satisfied by Alchian's model patterned after it. Alchian himself barred (c) as a criterion for determining the superiority of this theory over the traditional theory when he pointed out that both this and the traditional approach yield the same results.[9]

[8] Alchian, *JPE*, p. 213. It should be noted that "appropriate" in this quotation can only refer to those "optimal" conditions that can be known in advance by the economist from his knowledge of "generalized production and demand functions." Were it otherwise, Alchian's model would be reduced to the circular and empty proposition that only the most appropriate survive because those that survive are the most appropriate.

[9] Alchian states that with his "less restricted" axioms he can get "similar predicted observable circumstances." Enke explicitly notes that predictions are the same on the

If I am correct in asserting that none of these three conditions is met by Alchian's model, then the assumption of intense competition becomes a kind of *deus ex machina* introduced to make the model work, having no justification except to serve the purpose of replacing the human motivation so summarily dismissed from its former key position.

Competition cannot reasonably be expected to exist if men are presumed to act randomly. Under such circumstances its occurrence would depend on the constant and rapid creation of new firms, and without motivation it is hard to see why new firms should be created at all. Even if motivation is introduced in the modified form of a "desire to make profits," there would still be no reason why firms should appear in sufficient numbers in exactly the required industries or why there should be any response at all to many types of change, for example, to a general price rise due to government spending.[10] This type of response can occur only if firms seize on opportunities to make a little *more* profit—and this comes to the same thing, for all theoretical purposes, as the assumption that maximum profits are desired.[11] The existence of competition cannot be explained by Alchian's model, whereas it is explained in the traditional model with its quasi-empirical assumption that businessmen desire maximum profits.

There would be no need, however, for Alchian to *explain* the existence of intense competition providing that it were found to represent the facts of the real world with reasonable accuracy. But from the evidence at hand one cannot well conclude that a notable characteristic of our economic life is the prevalence of the kind of intense competition required to ensure that firms conforming to the "optimum conditions" of a competitive model have a higher probability of survival than large diversified firms in protected monopolistic positions.[12]

---

basis of either theory and the economist can predict "as if each and every firm knew how to secure maximum long-run profits" (*op. cit.*, p. 567). On the other hand, Alchian insists that "only by testing its predictive value by empirical investigation can the theory . . . be evaluated properly" (*AER*, p. 602). But if we get the same results with two theories, how will *empirical* research help us to choose the superior of them? The conclusions Enke draws about his gas stations certainly do not require the roundabout approach of viability analysis. I should be surprised, incidentally, if both theories would yield the same result when applied to the real world of monopolistic competition; but this is beside the point since Alchian and Enke insist that they do.

[10] *Cf.* Penrose, *op. cit.*, p. 813. It is my contention that an explanation of intense competition cannot be satisfactorily given unless an assumption equivalent to profit-maximizing behavior is made. The demonstration of this, however, falls outside the bounds of this rejoinder.

[11] When Alchian states that "desire to make a profit is not profit maximization" he obviously believes that the profit-maximizing assumption implies that individual firms must be able to ascertain what maximum profits are and actually to achieve them—a contention rejected here. For an excellent discussion of this question see Fritz Machlup, *The Economics of Sellers' Competition* (Baltimore, 1953), pp. 53-56.

[12] This especially applies to monopolistic positions resulting from the established reputation of the firm as a whole, and not primarily to special positions regarding particular products.

In other words, although useful results are sometimes obtained by assuming the existence of intense competition, the assumption itself is no more "realistic" nor "intellectually more modest"[13] than the assumption that individual firms try to maximize their profits. Both assumptions are highly artificial analytical devices, though very useful when appropriately used. The latter is applicable to a wider variety of problems and explains considerably more than the former. It takes account, albeit in an unrealistically pure and rigorous form, of the undoubted fact that businessmen are moved by a desire to make money, and it thus explicitly acknowledges human purpose. This is straightforward and has many advantages. The argument in favor of rejecting it on *a priori* grounds has to be powerful indeed.

II. *The Inappropirate Use of "Profit Maximization"*

The assumption that firms try to maximize their profits is rejected by Alchian, not for empirical reasons arising from a study of how firms actually do behave, but for logical reasons arising from the existence of uncertainty. He holds that in the presence of uncertainty no unique maximum profit position exists; that it is therefore impossible to give any meaning to the proposition that firms try to maximize profits; and that, consequently, a mere desire for maximum profits provides no guide for action. On the other hand, he is prepared to admit "motivated purposive behavior" and to recognize that firms are in business to make a profit, although apparently he feels that even this modified motivation is going a bit far.[14]

Once it is allowed that firms do try to make profits, it is not difficult to go a bit further and assume that in general they tend to try to make, if they think they can, a bit more profit than they are making. The question, then, is what difference does it make whether any individual firm knows the *best* way of going about its business—or indeed whether there is any "best" way before the event. This would make a great deal of difference if the economist were attempting to predict the actions of any particular firm. But the economist does not attempt such predictions—nor could he succeed if he tried, as Alchian rightly emphasizes. The economist uses the model of the profit-maximizing individual firm, not to predict the actual conduct of any firm, but merely as an analytical technique to assist him in understanding the effect of change on prices, production, employment, etc.[15] For this purpose it makes no difference

[13] "The approach suggested here is intellectually more modest and realistic . . . ," Alchian, *JPE*, p. 211.

[14] "The pursuit of profits . . . is the relevant objective. . . . Unfortunately, even this proximate objective is too high. Neither perfect knowledge of the past nor complete awareness of the current state of the arts gives sufficient foresight to indicate profitable action." Alchian, *JPE*, p. 218.

[15] At no point has Alchian demonstrated that his undeniably valid objection to the use of the profit maximization assumptions for the purpose of predicting individual firm behavior is an equally valid objection to its use in the analysis of the economy as a whole. Indeed, he suggests the contrary when he concludes that "most conventional tools and concepts are still useful, although in a vastly different analytical framework . . ." (Alchian, *JPE*, pp. 219-20). If the new framework were built on a more acceptable "axiom" than the old, it would be desirable; if it is not, as I am trying to show, then it seems to me that its creation becomes an unnecessary *tour de force*.

whether the conduct of any particular firm can be predicted, whether any firm at all can actually succeed in maximizing profits or even whether uncertainty makes it impossible to say that any particular profit is a maximum.[16]

The existence of uncertainty and the fact that different businessmen do evaluate risk differently is one of the reasons why firms do not all rush at the same speed in the same direction. In most cases differences in attitude toward uncertainty will affect the *rate* of movement in the economy, rather than the *direction* of movement. If firms respond at all to any of the disturbances usually analyzed by the economist—taxes, changes in demand or cost, etc.—they will move in the direction predicted by the economist using the traditional theory and *for the reasons assumed in that theory.*

On this level all that the traditional analysis does is to provide the economist with some insight into the type of action appropriate if losses are to be avoided or more profits made when a disturbance occurs. All he need assume is that most businessmen are intelligent enough not to act perversely, that there will always be some firms who prefer to make more money rather than less under otherwise equal conditions and thus will try to make such adjustments as they think appropriate to this end. If the *kind* of response which actually occurs in the economy when a change takes place corresponds to the *kind* of response appropriate in the model of the profit-maximizing individual firm, then the model has shown its worth for all the purposes for which it is normally used.

III. *The Treatment of Knowledge*

Alchian's model is inconsistent in its treatment of what economists and businessmen can know. In a footnote to my original article I presented a "summary" of the logic of his argument, which read in part: "Economists can know the conditions of survival. *Therefore economists can know what type of firm can escape negative profits.* Therefore economists can know what firms must do to make zero or positive profits. Therefore economists can know how maximum profits can be obtained."[17] In quoting this in his reply, Alchian omitted the sentence here italicized, presumably because he did not think it important. He then charged me with a *non sequitur* and with reversing his position.[18] But, although the words of the omitted sentence are mine, *the logical sequence is his,*[19] and it is precisely at this point that his entire argument, which starts out with the proposition that it is impossible to know how maximum profits can be obtained, reverses itself.

Alchian's insistence that economists can know "what types of firms or

[16] For this reason it is misleading to call it the "theory of the firm" at all—but that is another story. It should also be noted that uncertainty is only one factor destroying the applicability of the theory for predicting the actions of any particular firm.

[17] Penrose, *op. cit.*, p. 813.

[18] Alchian, *AER*, p. 602.

[19] "With a knowledge of the economy's realized requisites for survival and by a comparison of alternative conditions, he [the economist] can state *what types of firms or behavior* relative to other possible types will be more viable" (Alchian, *JPE*, p. 216, italics mine).

behavior . . . will be more viable" makes all the difference in the world to the argument. Consider his example of the football coach. If the condition of winning is merely the definition of winning, then of course we get nowhere. But if the football coach knows *what type of team or type of behavior can win*, can one seriously argue that he can have no idea as to how the required type of team or action could be achieved (even though he himself might not be able to achieve it)? If the omniscience of the economist extends to the type of firm or of behavior that can survive, it is mere quibbling to insist that he cannot advise as to how that type may be achieved.

Now my point is simply that economists do not and cannot have that knowledge of the long-run conditions of survival in the real world which is necessary to give Alchian's model the predictive power he claims for it. Given uncertainty and, in particular, purposive activity on the part of firms, the knowledge of both economists and businessmen about the type of behavior or of firm that will survive in the long run in the real world is equally limited and for much the same reasons. I readily agree that economists deal with, and do know, certain things businessmen do not deal with and consequently do not know; but Alchian is concerned, not with what people in different occupations *do* know, but with what people *can* know in an uncertain world. The proposition that uncertainty makes it impossible for businessmen to form reasonably accurate ideas as to how profits might be made, yet on the other hand does not interfere with the economist's ability to know what type of firm or activity can make profits, seems to me to be simply inconsistent. Uncertainty does not make the businessman's knowledge useless to him in his search for profits; and if the economist can predict anything about the real world of firms it is only because he has an idea about how firms are likely to respond to certain kinds of change relevant to their operations.

The weakness of the traditional analysis for predictive purposes in either the short or the long run is associated with the pound of *ceteris paribus*. It is clear, even from Enke's example, that viability analysis must use the same pound to exclude all unpredictable actions of firms in response to environmental changes which themselves change the conditions of survival. This is the chief import of the criticisms on pages 813-15 of my paper which Alchian believes miss the point. I did *not* do Alchian the injustice of implying that he thought that the economist could, or should be able to, predict the fate of any *particular* firm. On this point we are in complete agreement.

Attempts radically to alter the framework of existing theory are always likely to meet resistance, but progress comes from the interaction between innovation and resistance to innovation. I do not want my criticisms to be interpreted as an attack on the purpose of Alchian's original, provocative and able article—to approach some of the problems connected with uncertainty from a new direction. I am inclined to agree—if I may accept for once a biological metaphor of Alchian's—that "the marriage of the theory of stochastic processes and economics"[20] may be very fruitful; but let it be a

[20] Alchian, *JPE*, p. 221.

marriage by mutual consent with a community property agreement, and not a violent seduction.

Depreciation Allowances, Replacement Requirements and Growth: A Comment

In his recent article,[1] Profesor Eisner demonstrated that, when price changes are ignored, "Depreciation allowances exceed replacement requirements in growing economies or growing firms"; and that "... only when prices increase somewhat faster than real investment do replacement requirements approach the magnitude of depreciation allowances."[2] From this he concluded that "... the phenomenon of growth places on shaky ground those who would argue that depreciation allowances are insufficient to meet replacement requirements."[3] Eisner is literally correct in this conclusion, but it appears that he meant by "those who would argue" the many businessmen and accountants who contend that depreciation allowances are too low, for at the start of his paper he stated that their argument "... declares that the cost of replacing expiring equipment [thereafter referred to in his paper as replacement requirements] in today's inflated market is actually much greater than current depreciation charges, which are related to original cost of assets."[4] The inference is that the businessmen and accountants who contend that depreciation allowances are too low may be wrong under their own measurement criteria.

Before examining the validity of this inference, it is advisable to note the following concepts: (1) The calculation of depreciation involves the establishment of both a cost basis and an allocation basis. (2) Conventional accounting practice is the straight-line allocation of historical cost. (3) Eisner used the term "replacement requirements" to mean the allocation of replacement cost to the year of retirement.

Eisner was mistaken in his impression that the critics of conventional accounting practice advocate replacement requirements for the measurement of depreciation. Although some popular discussions of the subject do use the word "replacement" rather loosely, to my knowledge use of replacement requirements has not been advocated for calculating depreciation. Indeed, a survey of the literature reveals that all that has been advocated and discussed is a change in the cost basis, *i.e.*, the substitution for historical cost of either replacement cost or current purchasing power of historical cost.[5] Under either of

[1] Robert Eisner, "Depreciation Allowances, Replacement Requirements and Growth," *Am. Econ. Rev.*, Dec., 1952, XLII, pp. 820-31.

[2] *Ibid.*, pp. 830 and 831.

[3] *Ibid.*, p. 831.

[4] *Ibid.*, p. 820.

[5] See E. Cary Brown, *Effects of Taxation, Depreciation Adjustments for Price Changes* (Boston, 1952), particularly pp. 93-123, where the various proposals are discussed, and pp. 151-54, where replacement cost depreciation is estimated. For the accountant's treat-

these two methods the allocation basis would remain straight-line allocation. Therefore, Eisner's analysis, resting as it does on the use of retirements for the allocation basis, does not, as he inferred, confound those who are criticizing current practice, since they do not advocate *replacement requirements* as the basis of measurement.

Since Eisner has raised the cost of maintaining productive capacity (of which replacement requirements is a special case) as a possible basis for allocation, it may be of some interest to compare its accuracy for the measurement of depreciation with that of straight-line allocation. The latter is widely used solely because it is simple and objective; the accounting profession rationalizes the practice with the view that depreciation is ". . . a process of allocation, not of valuation."[6] Similarly, there is no *a priori* reason why the maintenance of productive capacity should result in the correct determination of income. Therefore, comparison of the two methods requires the establishment of a standard of comparison, a third method that is theoretically valid.

Such a criterion is to be found in neoclassical theory, where an asset's income is defined as the periodic payment in perpetuity that has a present value equal to the present value of the asset's expected future receipts.[7] Since depreciation is simply the difference between receipts and income, it follows that a definition of depreciation is implicit in the above. This definition can be stated directly as the present value of the future receipts at the start of the period less the present value of the future receipts at the end of the period with the period's actual receipts excluded from the latter quantity. Or, restated in the language of accountancy, the cost (of depreciable assets) incurred in realizing a period's revenue is the expiration in present value of the assets' expected future receipts. If this measure of depreciation, termed here the "economic life method," is accepted as valid, straight-line allocation and expiration of productive capacity may be compared for accuracy by determining how closely each approximates economic life depreciation. Such a comparison is made below through three illustrative cases, each of which assumes a different path for an asset's receipts over its life.

Before going into these cases, two points should be noted: (1) The cost basis of valuation is a fundamental postulate of accounting, and this postulate will not be violated. Specifically, although the expected receipts at time of purchase will be used to determine that portion of an asset's cost to be charged as depreciation in each year of its life changes in expected receipts over the asset's life will not modify its cost or the depreciation charge. (2) Since the issue here is the allocation of cost—not the cost basis—we need not become

involved in any debate over replacement versus historical cost. The latter will be used here.[8]

The first case considers the asset that functions perfectly until the day it falls apart—the case of the "one-hoss shay." Table I presents illustrative data

TABLE I.—DEPRECIATION OF A "ONE-HOSS SHAY"

Period	Receipts	Present Values[a]	Depreciation Based on		
			Productive Capacity	Economic Life	Straight-line Allocation
1	$10	$61.45	$ 0	$ 3.86	$ 6.14
2	10	57.59	0	4.24	6.15
3	10	53.35	0	4.67	6.14
4	10	48.68	0	5.13	6.15
5	10	43.55	0	5.64	6.14
6	10	37.91	0	6.21	6.15
7	10	31.70	0	6.83	6.14
8	10	24.87	0	7.51	6.15
9	10	17.36	0	8.27	6.14
10	10	9.09	61.45	9.09	6.15
Total			$61.45	$61.45	$61.45

[a] Present value at the start of each period of the remaining receipts discounted at 10 per cent.

based on these assumptions: (1) the asset has a ten-year life; (2) expected receipts vary with productive capacity; (3) the rate at which the receipts are discounted to arrive at their present value is 10 per cent; and (4) the asset's present value and its cost are equal at time of purchase. In Table I straight-line depreciation is a closer approximation of economic life than productive capacity. However, economic life moves between straight-line depreciation and productive capacity with the variation in the asset's life and in its rate of discount. Hence, as either or both of these parameters are increased, economic life moves closer to productive capacity.

It may be noted that some accounting texts, when discussing alternative mathematical rules for the allocation of cost, mention an annuity method, which in reality is our economic life method. However, in illustrating the method they assume, as with an annuity, that receipts are constant over time, and the inevitable consequence is a depreciation charge which increases over time. Since they recognize this consequence to be unrealistic and since they consider the method merely a mathematical rule, they reject it as a measure of depreciation.[9]

[8] Replacement cost could also be used. Given for each method the allocation of an asset's cost to any year, the depreciation on a replacement cost basis is derived simply by multiplying the historical cost charge by the ratio of replacement cost to it. A detailed treatment of replacement cost accounting by the writer is scheduled to appear shortly in the *Accounting Review* under the title "The Valuation of Accounts at Current Cost."

[9] For example, see W. A. Paton, *Advanced Accounting* (New York, 1941), pp. 284-86.

TABLE II.—DEPRECIATION OF AN ASSET WITH PRODUCTIVE CAPACITY DECLINING AT AN INCREASING RATE

Period	Receipts	Present Values	Depreciation Based on		
			Productive Capacity[a]	Economic Life	Straight-line Allocation
1	$10.00	$50.86	$ 1.27	$ 4.86	$ 4.62
2	9.75	46.00	1.58	5.15	4.62
3	9.44	40.85	1.98	5.35	4.62
4	9.05	35.50	2.49	5.50	4.62
5	8.56	30.00	3.10	5.56	4.62
6	7.95	24.44	3.93	5.50	4.62
7	7.18	18.94	4.83	5.29	4.62
8	6.23	13.65	6.05	4.87	4.62
9	5.04	8.78	7.58	4.16	4.62
10	3.55	4.62	9.46	3.09	4.62
11	1.69	1.53	8.59	1.53	4.66
Total			$50.86	$50.86	$50.86

[a] Derived by multiplying the cost of the asset with the percentage decline in receipts (which is equal to the percentage decline in productive capacity) during the period. The cost is $50.86, the present value at the time of purchase. This is the method that I presume Eisner would use in calculating depreciation.

In the second case, which Eisner considered the more general one, productive capacity declines at an increasing rate over the asset's life. Table II, which presents the illustrative data, is based on the same assumptions (with the exception of asset life) made in the first case, but here the receipts are derived from the function

$$C_t = 11 - 1.25^{t-1}$$

in which C is receipts and t equals time period. It can be seen that economic life depreciation first rises and then falls, but for the most part it remains close to straight-line allocation. As before, the agreement between these two measures of depreciation varies inversely with the life of the asset and with its rate of discount, but here it also varies inversely with another parameter—the shape of the receipts curve. As this curve approaches a straight line the agreement between economic life depreciation and straight-line allocation increases. Conversely, as these three parameters are increased, the difference between productive capacity and economic life depreciation is reduced. However, here the parameters must have considerably larger and less realistic values than in the first case for productive capacity to be superior to straight-line allocation.

The assumption of the two previous cases that expected receipts vary with productive capacity is in all probability not realistic. It is much more likely that the productive capacity of an asset expires little, if at all, over the period in which its receipts fall to zero. The decline in receipts during this period is due in part to increasing maintenance costs, but primarily it is due to the asset's increasing technological and/or demand inferiority in relation to new equipment, the demand inferiority arising from the discovery of substitutes

for the asset's products. The decline in receipts will take the form of a rise in factor costs and/or a fall in product prices.

This third case is illustrated in Figure 1, with the receipts function derived by assuming (1) that value added in the initial period is $50, with labor cost $40 and receipts $10, and (2) that the cost-price changes over the asset's life are equivalent to an annual 1-½ per cent increase in labor costs.[10] Hence, the receipts function is

$$C_t = 50 - 40(1 + .015)^{t-1}$$

and the asset life is 15 years. With this receipts function and with a 10 per cent rate of discount assumed, economic life depreciation falls continuously

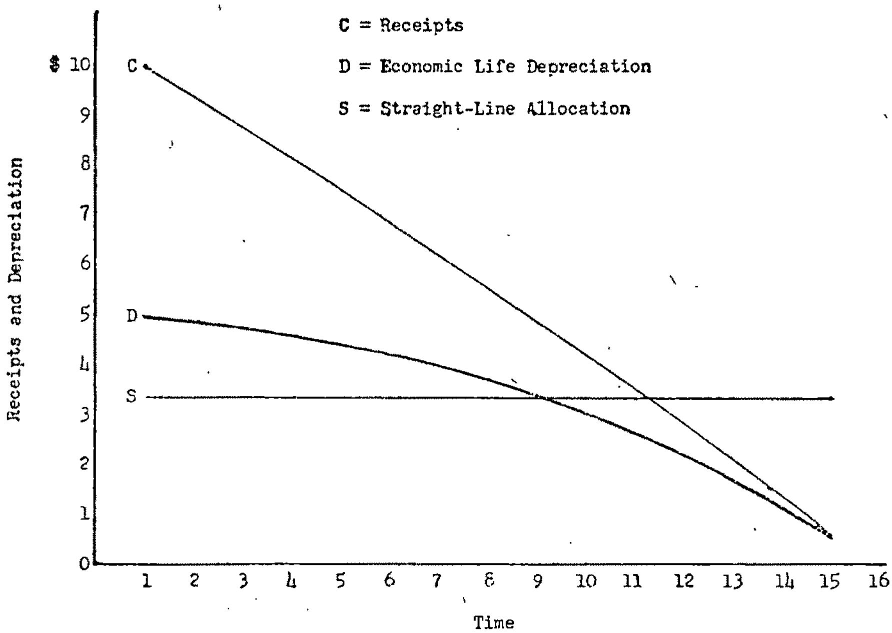

FIGURE 1. RECEIPTS AND DEPRECIATION OF AN ASSET WITH CONSTANT PHYSICAL PRODUCTIVITY AND DECLINING PROFITABILITY OVER TIME

over the asset's life. Consequently, since depreciation based on productive capacity is negligible in this case until possibly the last few years of the asset's life, straight-line allocation is for this asset by far the more accurate of the two methods.

It should be noted that, of the three cases presented, the approach to agreement in this case between economic life and straight-line allocations is by far the least sensitive to changes in the parameters. This can be seen as follows:

[10] These values were selected because: (1) A labor cost equal to 80 per cent of value added seems realistic for a manufacturing firm. (2) National output has been estimated to increase by about 3 per cent per year, with the increase fairly evenly divided between population growth and productivity gains. (3) Productivity gains give rise to a corresponding increase in real wages.

(1) The approximately linear decline in receipts in Figure 1 is not peculiar to the coefficients used in the illustration. It will hold for all values of the coefficients which are consistent with the basic assumptions underlying the third case. (2) Given this behavior for receipts, any change in the life of the asset, either by rotating the receipts curve around its intercept with the vertical axis or by shifting that curve, will not materially influence the form of the depreciation curve. (3) If the rate of discount is low, the depreciation curve will fall continuously at an increasing rate, as shown in Figure 1. However, if the rate is high, the depreciation curve will first rise and then fall, with all but the last few years close to the value for straight-line allocation. To illustrate this, assume a 25 per cent rate of discount and a receipts function of

$$C_t = 50 - 30(1 + .015)^{t-1}$$

in which case the asset has a useful life of 24 years and a cost of \$51.13. The straight-line depreciation is \$2.13, and the economic life depreciation rises and falls in the interval between \$2.00 and \$2.50 during the first nineteen years and then falls to zero.

In conclusion, if economic life is a valid measure of depreciation and if the assumptions of the third case are, in fact, a reasonable basis for predicting the behavior of an asset's receipts, then straight-line allocation is superior to productive capacity as a measure of depreciation. However, if the fall in an asset's receipts parallels the fall in its productive capacity, the superiority of straight-line allocation does not hold as the values of the parameters become relatively large.

Finally, there has been considerable dissatisfaction on the part of many businessmen, economists, and accountants with the two principal accounting conventions—historical cost and straight-line allocation. It is hoped that this comment may prove useful in the evaluation of the latter convention.

MYRON J. GORDON*

* The author is assistant professor of industrial management, Massachusetts Institute of Technology. He has benefited from the criticisms offered by Professor Eisner of an earlier draft of this comment. In particular, it was pointed out to what extent economic life depreciation could vary in the first two cases with an asset's life and rate of discount.

Rejoinder

Mr. Gordon apparently does not challenge the "literal" correctness of my argument. He does raise some question as to its relevance. I should like to attempt briefly to defend the relevance of the relation between depreciation and replacement both to the income-profits setting in which I placed it in my article and to economic theory in general. In doing so I shall venture certain criticisms but not outright rejection of the "economic life method" of depreciation described by Gordon.

1. *"Replacement Cost" and Profits*

As Gordon implies, "popular discussions" do appeal "rather loosely" to the concept of replacement requirements in the argument against current depreci-

ation practices. During the years since the second world war, in the face of repeated reports of record-breaking corporate profits there has been an important campaign to impugn official profits figures. This campaign has been based chiefly on the assertion that replacement cost actually exceeds allowable depreciation charges. For example, Mr. Enders M. Voorhees, chairman of the Finance Committee of the United States Steel Corporation, has declared:

"The item, 'Added to Cover Replacement Cost,' on U.S. Steel's income statement is designed to restore realism in the measurement of depreciation cost in the light of the dollar debasement transpiring between the time facilities were originally purchased and current accounting periods. . . . If a business is to continue it is necessary to recover the purchasing power of sums originally invested in tools of production *so that the tools may be replaced as they wear out.*"[1]

We may cite, in similar vein, the Machinery and Allied Products Institute's *Capital Goods Review* of November 1952, which devotes itself to "the tendency of conventional accounting procedures to overstate profits in an inflationary period." This publication adds (page 2):

"The overstatement arises, of course, from the practice of charging the original, or historical, cost of the inventory and fixed assets consumed in current production rather than the cost of replacing them. When replacement costs are rising, original costs, reflecting earlier, and hence lower, price levels, are insufficient for the *physical restoration of the assets used up in production* [italics added]."

Turning to the ranks of academic economists we may quote from Theodore Morgan's *Income and Employment* (New York, 1952, 2nd ed.): "But a considerable part of this profit rise [from \$6.5 billion in 1939 to \$39.8 billion in 1950] is an illusion. Profits are figured after *legally allowed* depreciation charges are subtracted. These charges are clearly far too low to replace capital: the costs of capital have more than doubled since before the war so that both current reserves and reserves accumulated during wartime are insufficient to *replace equipment wearing out and worn out*" (pp. 369-70—italics added in last sentence).

As Gordon suggests, popular advocates of the use of "replacement cost" are inconsistent about the concept they have in mind. They intimate broadly, as may be seen above, that depreciation allowances are not enough for replacement of the tools "as they wear out." (Actually, as my article indicated, under reasonable assumptions as to how tools "wear out," depreciation charges are likely to be more than ample for such replacement.) Yet, as Gordon points out, those urging "replacement cost" would not be satisfied with charging *the cost of replacing those assets currently requiring replacement*, although it is in terms of this cost that they make their appeal. They offer proposals to adjust currently allowable depreciation charges by price indices or to revalue assets in accordance with current market price, which indicate clearly that they would really like to base depreciation charges on *the cost of replacing all assets*

[1] Statement before the Subcommittee on Profits of the Joint Congressional Committee on the Economic Report, Washington, D.C., December 21, 1948. (Italics added.)

on the books. Whatever the general merits of such proposals, their proponents might spare us the quite fallacious accompanying lament that depreciation accounts would otherwise be insufficient to prevent firms from fading away.

Gordon is thus correct in observing, in effect, that when critics of conventional accounting practice get down to proposing specific changes in depreciation accounting (as opposed to general appeals aimed at the lay public) they do not advocate anything as useless from their point of view as the allocation of replacement cost to the periods in which replacement costs must be met. However, it is a bit difficult to see the justification for these critics in using "replacement" as a cost basis and then discarding it as an allocation basis. The reason for paying attention to "replacement" cost is presumably, as implied in the quotations above, that it enables firms to account correctly for the maintenance of assets in some "real," physical sense. In this context, replacement costs at any given time can only be relevant to that portion of the firm's assets requiring replacement at that time. Advocating replacement for the cost basis but not for the allocation basis strikes me as endeavoring "to have one's cake, and eat it too." I find it curious to note that Gordon sets himself a higher standard of consistency in his comment than he is apparently willing to impose upon advocates of "replacement cost." For in his presentation of the "economic life method" Gordon uses the one criterion, discounted value of future returns, for both his cost basis and his allocation basis.

I should classify myself as agnostic on the issue of whether the cost of replacing "worn out equipment" (or "the assets used up in production") should be a criterion for the adequacy of depreciation charges. I should demand, however, that advocates of "replacement costs" offer an unambiguous usage of this concept and face its mathematical implications.

2. *A Further Consideration of "Depreciation Based on Economic Life"*

I should classify myself as agnostic as well on Gordon's alternative suggestion or criterion for depreciation charges: "the present value of the future receipts at the start of the period less the present value of the future receipts at the end of the period." Depreciation in conformity with this criterion, which Gordon calls "the economic life method," has, I believe, many facets which Gordon has not explored adequately.

For one thing, current value must really vary with *expected* future receipts, since, of course, future receipts cannot be *known* currently. But this means that if business expectations improve, values of assets, *cet. par.*, rise. Would Gordon then have business firms note an "apreciation credit" which would be an addition to their current profit figure? He would not; but on what justification, other than that "the cost basis of valuation is a fundamental postulate of accounting"?

Secondly, while Gordon is concerned directly only with the constant price portion of my discussion, it should not be forgotten that the entire issue has developed on a policy level only in connection with general increases in prices. How then would the "economic life method" work out with rising prices? If as

a first approximation we assume that the monetary amount of future returns is expected to increase in direct proportion with price increases, we may well find that in a period of rising prices the "values" of assets would rise in their early years, if by "value" we mean the sum of discounted, expected, future returns. Then we might again be warranted in applying an "appreciation credit."[2]

Thirdly and fundamentally, however, I should like to take issue with both the substance and the implicit concept in Gordon's claim that the "economic life method" is appropriate for evaluation of other methods of depreciation because it is "theoretically valid." For it should be observed that economic theory is no monolithic structure. Theoretical concepts which are useful and preferable in approaching one type of problem may be quite inappropriate for another. All Gordon can properly assert is that straight-line allocation of original cost gives a rough "fit" to a curve measuring loss of value of an asset when this loss of value is defined as the loss in discounted value of known future returns (and when length of life of assets and the function indicating the rate of decline of productive capacity or returns are of certain particular parameters). But economic theory may suggest the utilization of a variety of methods of charging depreciation, depending upon the problem at hand. If we are concerned with the capacity for current output, as in certain problems of economic development or in problems of comparing actual output to potential output, we should probably find a measure of depreciation in terms of loss of productive capacity to be much more useful for analytical purposes.[3] Similarly, in application of the acceleration principle it would be more "theoretically valid" to rule out immediately as independent of increases in current demand that part of investment equal to replacement requirements as I defined them in my article than that part of investment that would maintain value intact in the sense Gordon defines "value." Finally, the theoretically appropriate measure of depreciation for purposes of income measurement, as I suggested in my article, should take into account "basic social, political and moral problems of the rights of ownership."

3. *Further Experimentation with Receipts Functions and Their Parameters*

Gordon glosses over certain other complications of his economic life method by failing to set forth general equations or formulae for depreciation charges in accordance with this method. Let us supply such general equations.

First, let V_t equal the value of an asset at the beginning of period t.

Let us designate V_{t+1} as the value of this asset at the beginning of the period $t+1$.

[2] This should certainly call into question Gordon's assertion (footnote 8) that "the depreciation on a replacement cost basis is derived simply by multiplying the historical cost charge by the ratio of replacement cost to it."

[3] Evsey D. Domar, for example, has suggested some interesting implications for our growth-of-productive-capacity models inherent in just the relation between replacement requirements and depreciation allowances under consideration, in his stimulating "Depreciation, Replacement and Growth," *Econ. Jour.*, March 1953, LXIII, 13-24.

Then let us designate U_t as that part of the value of the asset used up or dissipated in the period t.

From the above it follows that

$$U_t = V_t - V_{t+1} \tag{1}$$

Now, let a equal the length of life of the asset, let g equal the age of the asset at the beginning of period t, let s equal the discount ratio to apply to future returns [if $i =$ the "rate of discount," $s = (1 + i)^{-1}$], and let Y_j equal the returns expected on the asset in the period j.

Then it follows that

$$V_t = \sum_{j=t}^{t+a-g-1} Y_j s^{j-t}. \tag{2}$$

Similarly,

$$V_{t+1} = \sum_{j=t+1}^{t+a-g-1} Y_j s^{j-(t+1)} \tag{3}$$

In the one-horse-shay type asset we may assume, as does Gordon, that the amount of returns expected in each year of the life of the asset is the same. We may then substitute Y, designating this constant return, for Y_j, in (2) and (3). Then substituting (2) and (3), thus modified, into (1), we obtain

$$U_t = Ys^{a-g-1}. \tag{4}$$

Inspection of (4) now reveals readily that the amount of value actually used up in any period varies directly with the values of s and g and inversely with a (it should be recalled that all reasonable values of s will be between 0 and 1; the larger the value of $a - g - 1$, the smaller the value of U_t). Let us try values for s and a which may be believed to square with the real world and see if our conclusions are quite the same as Gordon's.

First, we should note the well-known business goal of rapid "pay-outs" on capital investment. A five-year pay-out criterion for many types of capital is quite common and while this time dimension varies (particularly with the ratio of plant to equipment), it is probably safe to conclude, at least for crudely illustrative purposes, that businessmen will not undertake capital expenditures, on the average, unless the sum of the absolute values of expected returns in the next five years is equal to the cost of the asset. Let us now assume that the length of life of the asset is not ten years, as assumed by Gordon, but 30 years, in accord with various estimates of the mean length of life of capital assets in the United States.[4] We then find that assets of a one-horse-shay variety which "pay-out" in the businessman's sense in five years but actually last 30 years must give returns subject to a discount ratio of about 80 per cent if the sum of future returns is to equal the original cost

[4] Domar suggests this figure of thirty years (*ibid.*, p. 5, fn. 1), citing Solomon Fabricant, *Capital Consumption and Adjustment* (New York, 1938), p. 34, and "estimates obtained orally from the United States Department of Commerce."

of the asset.[5] We may now rework Gordon's Table I and note that an asset promising receipts of $10 per year for thirty years would be worth $50 initially, and would decline to $49.985 at the end of the first year. At the end of ten years the asset would still be worth $49.23. After twenty years, two-thirds of the life of the asset, it would still be worth $44.63, having lost little over 10 per cent of its original value. Even after 25 years, our asset has lost an amount equal to less than a third of its original cost, its present value equalling $33.61. It is clear that with these parameters, measuring loss in value in this way instead of considering loss in productive capacity would not move us particularly far from the A-1 case which I associated with one-horse shays.

Similarly, it can be shown that Gordon's Table II when reworked in accordance with a *25 per cent* rate of discount and 30 year assets will show a loss of value over time which fits my general *A* category of assets declining at an increasing rate. Thus we will note in Table II*, which is entirely analogous to Gordon's Table II except for the changed parameters, that the value of the asset measured by Gordon's "economic life method," drops quite slowly when the asset is new. Indeed, when the asset has lived half its life its value has dropped only from $400.40 to $356.16, a decline of but 11 per cent.

Table II* indicates that in twenty of the asset's thirty years productive capacity expiration comes closer to economic life depreciation than does straight-line allocation. The mean deviation of straight-line allocation from economic life depreciation is $5.01; the mean deviation of expiration of productive capacity from economic-life depreciation is only $4.35. However, more important, when we consider the matter in the relevant context of growth in which I set the problem, we find that in every one of the first 13 years of the asset's life, expiration of productive capacity is a closer approximation to economic life depreciation than is straight-line allocation. It is only in the later years of the asset's life that substantial discrepancies between expiration of productive capacity and economic life depreciation develop. But the nature of the phenomenon of growth is such that older assets are not quantitatively as important as newer ones. For example, if the rate of gross investment were growing at three per cent annum (a rate of growth which Gordon indicates is acceptable, in footnote 10), and all assets had lives of 30 years, only 39 per cent of the assets on the books at any one time would be more than 15 years old. On the other hand, it is to be noted that the major part of the excess of straight-line allocation depreciation charges over economic life depreciation (as over expiration of productive capacity) occurs in the early years of the life of the asset, which, when assets of all ages are aggregated, brings about an "excess" of depreciation charges analogous to the one discussed in my article.

Gordon's final "receipts function" which he derives from the growth of the economy as a whole strikes me as arbitrary in the extreme. I fail to see a

[5] Assuming that annual returns are equal to unity, the discount ratio may be obtained by solving for s the expression:

$$\sum_{n=0}^{a-1} s^n = 5.$$

(6)

TABLE II*.—DEPRECIATION OF AN ASSET WITH PRODUCTIVE CAPACITY DECLINING AT AN INCREASING RATE

[Gordon's Table II reworked with assets of 30 years and rate of discount of 25 per cent:

$$C_t = \frac{807.8 - 1.25^{t-1}}{10} = \text{Receipts in the period t} \qquad (7)]$$

Period t	Receipts C	Present Values V	Depreciation Based on Productive Capacity R	Depreciation Based on Economic Life V	Depreciation Based on Straight-line Allocation D
1	$80.68	$400.40	$ 0.12	$ 0.75	$ 13.35
2	80.65	399.65	0.15	0.91	13.35
3	80.62	398.74	0.19	1.09	13.34

30	16.16	16.16	80.20	16.16	13.34
Total			$400.40	$400.40	$400.40

reasonable basis for translating increased productivity though the rest of the economy taken as a whole into increased costs of operating individual assets of individual firms. Implicit in Gordon's functional relation and parameters must be numerous assumptions about the distribution of an aggregative increase in productivity, the manner of technological change, the nature of obsolescence and dynamic price-cost relationships.

Actually, the expected receipts from certain capital assets may well decline

over time in the almost linear fashion indicated by Gordon's arbitrary function. For very many other assets they may not. This is something to be studied empirically, although it might be very difficult to go beyond accounting rules in imputing receipts to particular assets. In relating loss in value of assets based on a falling time path of expected future receipts to actual depreciation charges one would then have to reckon with depreciation charges as they are actually made for each asset. One might then find, as I suggest in my article in relation to declines in productive capacity, that many assets, the values of which declined in the manner that Gordon here indicates, would actually be covered by some form of "accelerated amortization" or of non-straight-line system of depreciation.[6]

ROBERT EISNER*

[6] I should add that I am a bit confused as to the nature of the distinction that Gordon makes between productive capacity and receipts. His reference to productive capacity which "expires little if at all over a period longer than the receipts life of an asset," is particularly puzzling. For aside from a general shortage of effective demand it hardly seems to make economic sense to refer to an asset as having productive capacity when it cannot be economically utilized.

* The author is assistant professor of economics, Northwestern University. He is indebted to Robert H. Strotz, Edward C. Budd, Richard B. Heflebower, and Bert G. Hickman for helpful comments and to Burton A. Weisbrod for statistical computations.

The Shape of the Average Cost Curve: Comment

With a recent article in this *Review*,[1] Professor Eiteman resumes his particular variant of antimarginalism and revives a controversy he had originally initiated in 1947.[2] Eiteman and Guthrie state that ". . . orthodox price theory is not valid if businessmen believe [their average total cost] curves to be shaped so that their least cost points are at or near capacity. . . ."[3] They find that the overwhelming bulk of businessmen questionnaire respondents do believe the shape of their average cost curves to be as thus described and therefore conclude that the replies "do not support marginal theory. . . . If the beliefs of businessmen in general coincide with those included in this sample, it is obvious that short-run marginal price theory should be revised in the light of reality."[4]

The logical structure of the Eiteman-Guthrie argument is clear. If business-

[4] *Ibid.*, p. 838.

men believe the least cost point falls at or near capacity, marginalism is not valid. Businessmen do believe this. Therefore marginalism is invalid and price theory should be revised. The initial postulate, however, that such beliefs on the part of businessmen vitiate marginal price-output theory, is as fallacious today as it was when first advanced in 1947.[5] The sole reason Eiteman-Guthrie advance to support their statement that such beliefs on the part of businessmen subvert marginalism is that when businessmen hold such views regarding cost behavior ". . . the short-run marginal cost curve for a product always lies below the average cost curve at all levels of operation short of capacity. The result is that the marginal cost curve cannot intersect the marginal revenue curve (1) if the average revenue curve is horizontal, or (2) if the average revenue curve is high and relatively elastic."[6] Eiteman-Guthrie thus take the well-known graphic marginal cost-marginal revenue intersection to be the crux of marginalism and declare orthodox theory invalid if that equality is not forthcoming in the usual manner.

Taking the replies of their respondents at face value, the following may be offered in rebuttal:

1. If the least cost point is believed to occur "near" rather than "at" capacity, the orthodox demonstration of the equilibrium position of the firm is likely to hold even to the relatively unimportant detail of graphic portrayal via the conventional marginal cost-marginal revenue intersection. For as soon as the average cost curve is admitted to start curving upward, even slightly, before termination at "capacity," the marginal cost curve, which rises above the average cost curve after the latter has passed its minimum value, shoots upward with great rapidity until, at capacity, it is likely to be far higher than the average cost curve. Thus the usual portrayal of the marginal intersection is likely to occur even if the least cost point is "near" capacity.[7] It is still possible, of course, that the demand curve facing the firm may be so high and elastic that marginal revenue never falls as far as the value of marginal cost at "capacity"; in this case we do not obtain the graphic marginal intersection in the usual manner and the example becomes substantially identical with that in which the least cost point is believed to occur "at" capacity.

2. If the least cost point is believed to occur "at" capacity, marginal cost will be equal to average cost at that output level and both curves will end

[5] *Cf.* the conclusive arguments of Bishop and Haines, cited in footnote 2 above. There is, in fact, little than can be advanced in refutation of the Eiteman view that has not already been stated by Bishop and Haines.

[6] Eiteman-Guthrie, *op. cit.*, p. 832.

[7] For a textbook graphic portrayal of such a case, in which the least cost point is placed at the extreme of *95 per cent* of capacity, see Allen M. Sievers, *General Economics* (Chicago 1952), p. 466. Sievers, in fact, uses this model as his typical firm throughout and encounters no difficulty in employing it to illustrate the conventional marginal cost-marginal revenue intersection in all of the customary market situations. Sievers' example is far more extreme than that illustrated by Eiteman-Guthrie's Figure 6, which they claim "does not support maginal theory"; in their Figure 6 the least cost point occurs at approximately 75 per cent of capacity. The corresponding marginal cost curve, which Eiteman-Guthrie do not draw, will rise to a value at capacity which exceeds the original value of their average cost curve as drawn.

there.[8] Thus, providing the demand curve facing the firm is sufficiently high and elastic, there will be no conventional marginal cost-marginal revenue intersection.[9] However, this in no way invalidates marginalism, of which the usual graphic intersection is but a superficial aspect. Marginalism is a deductive principle of the end-result to be expected from profit-maximizing behavior, merely claiming that the entrepreneur will, if possible, produce additional output if the added receipts expected exceed the added costs which it is thought will be incurred. (The identical conclusions can easily be demonstrated via the exclusive use of total cost and revenue, or average cost and revenue, with no mention at all of the marginal quantities involved.) Eiteman-Guthrie make no attempt to refute conventional marginalism thus stated; indeed, to do so they would have to show that firms operating under the posited nonintersection conditions would generally produce at *less* than capacity, for production at capacity output is in accordance with rather than a refutation of orthodox theory.[10]

3. We have seen many cases before in which there are discontinuous curves and in which no marginal cost-marginal revenue intersection exists. Continuous curves either (a) assume continuous data, or (b) are a distortion of reality in the interest of explanatory clarity. The fact that economists use such curves to discuss data that is essentially discrete does not invalidate marginalism; it merely means that the real world is more complicated than our "ideal-type" construct which is little more than a first approximation to reality.

4. If it is assumed (a) that businessmen attempt to maximize a single magnitude—money profit—or some complex of objectives which can be ordered on a scale and termed "satisfactory" profit or "net advantages," (b) that they have adequate knowledge regarding the relevant variables, and (c) that they act rationally, then the essentials of present-day marginalism are *already implied* regardless of the existence or nonexistence of the superficial marginal cost-marginal revenue intersection. Eiteman and Guthrie have concentrated their attack upon trivia rather than upon substance.

LAWRENCE S. RITTER*

[8] As Bishop has pointed out, strictly speaking the marginal cost curve ends in indeterminacy at capacity. Cf. Bishop, *op. cit.*, pp. 611-12.

[9] If the demand curve is not sufficiently high and elastic, we get the usual intersection of the marginal curves. Eiteman-Guthrie imply that declining average costs are, in some way, incompatible with marginalism, although they never state this view explicitly. That such is not the case can easily be seen by a perusal of any standard work, such as, for example, Joan Robinson, *The Economics of Imperfect Competition* (London 1933), in which most marginal cost-marginal revenue intersections occur during the phase of declining average costs.

[10] The definition of capacity by Eiteman-Guthrie as excluding all overtime work and payments is a partial begging of the entire question. Orthodox marginalism can offer an explanation of a failure to increase output and therefore can at least partially explain why at any one time some firms are and some are not producing *beyond* "capacity." It is not the purpose of this note, however, to disparage the usefulness of the questionnaire results *per se*, but rather to criticize the implications the authors draw therefrom, even if the survey is taken at face value.

* The author is assistant professor of economics at Michigan State College.

Comment

In a recent issue of the *Review* an attempt was made to controvert certain notions about the rôle of the firm's average cost curve by the procedure of questioning businessmen on the shape of the curve. The authors are clear to point out that they are not interested in the actual shape of the cost curve but rather in the opinions of businessmen as to the shape, since these are claimed to influence decisions as to output. It is not clear how seriously the authors regard the results of the survey. At successive stages the results are regarded as constituting an attack on "marginal price theory" (p. 832), "conventional marginal price analysis" (p. 837) and finally the much more modest goal of "short-run marginal price theory" (p. 838).[1] However, in a table summarizing the replies of businessmen, the authors classify cost curves as "supporting or not supporting marginal analysis," and place the majority of responses in the latter category.[2]

Replies by 366 out of 1,000 companies reveal that about 61 per cent of businessmen *believe* that short-run average costs "are high at minimum output, and that they decline gradually to capacity at which point they are lowest" (p. 835, see curve labelled 7). The replies of the other businessmen indicate a preference for a cost curve not too far from this conception. The authors interpret these results as substantiating their position against marginalism. They insist that:

> The reasoning of marginal price theory is valid if businessmen *believe* curves to be shaped as theorists assume, even though the curves are actually shaped as opponents contend; conversely, orthodox price theory is not valid if businessmen *believe* curves to be shaped so that their least cost points are at or near capacity, even though the curves really have the shape which conventional theorists maintain (p. 832).

If businessmen make decisions on the basis of a cost curve differing from conventional analysis, which contention supposedly emerges from their investigation, then they insist that conventional analysis must fall (or be revised?—see last paragraph, p. 838).

It is not clear to this writer what significance can be attached to this investigation or if any significance at all can be attached. It appears that the investigation contains misconceptions of marginal analysis, improper use of theoretical terms and errors of methodology.

1. Actually the authors have made no case whatever against marginal analysis. Behavior on the basis of their short-run average cost curves can be readily explained by the tools of marginal analysis, and R. L. Bishop did pre-

[1] The authors seem unaware that they have actually provided an evaluation of their investigation and that they have drawn implications that are anything but obvious. The authors should recognize that they fail to stick to their avowed purpose of describing the methods and reporting the results of their study (p. 833). This by itself would be innocuous, if unenlightening.

[2] In this classification the authors ignore Bishop's devastating criticisms of an earlier article by one of the authors. See R. L. Bishop, "Cost Discontinuities, Declining Costs, and Marginal Analysis," *Am. Econ. Rev.*, Sept. 1948, XXXVIII, 607-17.

cisely this in a rebuttal to a previous article by one of the authors.[3] Bishop indicated how the equality of marginal revenue and marginal cost must be replaced by more fundamental marginal conditions (expressing maximization of profits) to handle outputs where marginal revenue and cost, which are derivatives of the total revenue and cost curves, do not exist. This is the case at the point of minimum cost where the cut-off of the total cost and corresponding average cost curves prevent the existence and equality of both a right-hand and left-hand limit necessary for differentiability and the existence of marginal cost.[4] But this equilibrium output is still given by the more fundamental condition of profit maximization, which is what MR = MC is meant to depict for "normal" curves. The authors mention this latter condition only (p. 832) and thus foster the impression that this is what is meant by marginal analysis. But this is only true under the suitable differentiability conditions, and it is surprising that this would have to be reaffirmed after Bishop's adequate discussion.[5] In effect the authors nowhere present a test of either the assumptions of marginal analysis[6] or its predictions as to output and price policy. Apparently the authors are really testing a hypothesis as to cost and "capacity," which has no bearing on marginal analysis, but they never state the issues carefully.

2. An alternate interpretation of the article is that the authors reject marginal cost pricing in favor of what has come to be known as "full-cost" pricing. Their use of an average cost curve would seem to bear this out, and in particular their statements as to businessmen acting on the basis of what they believe to be the average cost curve reflect this belief, since in the short-run intrafirm equilibrating process it is only marginal curves that are relevant for price and output policy according to marginal analysis, and the position of the average cost curve is price-determined. But the authors make no attempt to relate businessmen's belief in their particular average cost curve to their actual behavior, and thus distinctly leave the impression that the average cost curve they depict is meant only to draw an inference as to the marginal cost curve (see p. 832, par. 1). The authors, however, are never really clear as to the respective rôle of the marginal and average cost curve in short-run (or any run) marginal analysis. In any case their presentation can be made compatible with marginal analysis, and in fact they do not reject the equilibrium output indicated by marginal analysis for their cost curves.

3. In their questionnaire the average cost curve is defined as "a line on a graph which shows the cost per product at each possible scale of operation from the minimum to the maximum *(excluding all over-time work)*" (p. 833). But overtime is surely an important way in which to effect short-run changes

[3] *Loc. cit.*

[4] R. Courant, *Differential and Integral Calculus* (New York, 1946), p. 97.

[5] *Op. cit.*, pp. 609-10. In implying that businessmen normally operate at minimum cost, where marginal cost in their assumed cost curve does not exist, the authors also imply a certain shape and position of the marginal revenue curve (p. 832). This hypothesis, however, is not tested in their questionnaire.

[6] As for instance stated in R. A. Gordon, "Short-Period Price Determination," *Am. Econ. Rev.*, June 1948, XXXVIII, 265-88.

in output. It should be pointed out that although the economist's cost curve depicts cost per unit product vs. rate of output, the rate must in practice be averaged over a large enough time interval so as to smooth over the effect of institutional time indivisibilities such as daily alternation of work and rest. Overtime then certainly does increase the rate of output and must be included in any analysis of the firm. The authors cannot define cost in a peculiar manner and then test a proposition as to the economist's cost curve, which is something different, on the basis of it.

4. Since fundamental errors in definitions and the conception of marginal analysis lie at the base of the study under consideration, it may be amiss to bring in a methodological point, but certain statements of the authors indicate a basic methodological misorientation with respect to the nature of a scientific theory such as marginal analysis. The authors feel apparently that for marginalism to be valid businessmen must somehow operate explicitly with revenue and cost curves and carry out the relevant marginal operations. This is more explicitly stated in a previous article by one of the authors where he states that a particular pattern of business behavior refutes marginal analysis since "In making such decisions, businessmen do not construct marginal revenue and marginal cost curves nor do they operate at a scale of operation that such curves would indicate if they were drawn."[7] I should hope that businessmen do not try to construct such curves at the present time, considering the time, effort and theoretical difficulties involved! Marginal price theory is not (at least yet barring the success of linear programming) a guide for businessmen to follow. Rather it is a theory explaining the behavior of firms whether or not they are aware of the theory; empirical tests relevant to the accuracy of output and price predictions are of course very much in order.

Moreover, it is not clear that what businessmen reply to a questionnaire constitutes a reliable guide to their actions. At any moment their scale of output is the end result of a complicated process of adjustment, most of which has been effected. Naturally any businessman might be expected to ignore most of this adjustment when queried and tend to oversimplify or misinterpret a present situation. At the very least an empirical study of business decisions should cover some period of time in order to trace the adjustment mechanism. It is thus an open question what significance a belief at a particular point of time has for business decisions. But I personally share Milton Friedman's skepticism as to the ability of most businessmen to accurately explain their behavior even over a period of time. Fortunately marginal theory does not require psychological introspection for its validity to be established; rather like any scientific theory it is to be judged as to the accuracy of the results it predicts.[8]

5. The investigation does not "contradict" marginal analysis. It does seem

[7] W. J. Eiteman, "The Least Cost Point, Capacity, and Marginal Analysis," *Am. Econ. Rev.*, Dec. 1948, XXXVIII, 899-904.

[8] See Milton Friedman, "Comment" on the essay by Richard Ruggles, "Methodological Developments," in B. F. Haley, ed., *A Survey of Contemporary Economics*, Vol. 2 (Homewood, Ill., 1952), pp. 455-57. See also a related comment in the same volume by A. G. Papandreou, p. 206.

to be faulty, however, even if interpreted on a more modest scale. No conclusion can be drawn as to the economist's average cost curve and its relation to capacity, since neither is adequately defined; and if the authors support "full-cost" pricing their questionnaire is not adequately framed to test this point. But it is not clear what significance can be given to businessmen's reactions in testing any conception as to price and output determination. The authors, however, are never clear as to what they are doing and what their terms mean, and their methodological misconceptions hardly constitute *the* point of criticism, as they might have otherwise.

Comment

How unfortunate that the exotic and pugnacious pleasures of windmill-tilting have led Professor W. J. Eiteman to assert that the results of his unusually intelligent and unloaded questionnaire on the imagined shape of average cost curves constitute empirical refutation of something called "marginalism," an old enemy of his.

His results do overthrow the conventional U-shaped cost curves of conventional textbooks[1] and conventional review articles. Amen, and so much the better. But the U-shaped curves are not marginalism; they are merely pretty pictures, just as the hourglass figure is not the human female but the "foundation garment." We like our cost curves parabolic (*i.e.*, U-shaped) because it is so easy for the rudimentary mathematician to derive and visualize average-marginal relations from this particular shape. But marginalism as such assumes no curve types—U or V or W or any other. All are grist to the mill. Any of Eiteman's eight curve types is just as marginal (or just as antimarginal) as any other. His error lies in treating certain curve types as "supporting" and others as "not supporting" the "marginalist hypothesis." (References?) Strange things result. This writer, for example, considers himself a marginalist of sorts, albeit lukewarm and long-run.[2] Yet in classroom presentation, he likes to work with curves of the two types (6-7) found most realistic by Eiteman—and labelled "antimarginalist"! (What, in particular, is "antimarginalist" about the U-shaped type 6?)

The issue between marginalists and averagists in cost and price theory is a real one. Marginalism is not pure tautology, despite some unguarded statements by overenthusiastic proponents; it is perfectly possible for businessmen to act in an antimarginalist manner. Whether they do so act or not depends not on curve types but on whether they do (or should) base their price and output policies on marginal rather than average cost considerations, *when marginal and average costs diverge materially*. On this topic, the researches of Eiteman and Guthrie tell us little or nothing. And necessarily so, as a glance

[1] Among the notable exceptions is Lorie Tarshis' *Elements of Economics* (Boston 1946). Is Tarshis an antimarginalist because he foresook the U-shaped cost curve in favor of something like a beaver's front tooth?

[2] M. Bronfenbrenner, "Imperfect Competition on a Long-Run Basis," *Jour. Bus.*, Apr.

at his curve descriptions will show. The two most popular types (6-7) and one other type (8) are described so as to render AC and MC practically coincidental for most of the relevant parts of their ranges.[3] Where this is true, the whole marginalist-averagist controversy becomes a completely terminological or sham battle!

The empirical significance of Eiteman and Guthrie's results, as I see them, has nothing to do with the marginal controversy. Apparently the businessman's imagined zone of maneuver in adjusting output downward when price falls or when cost rises is conceived by the businessmen themselves as much smaller than textbook diagrams would lead us to imagine. Output restriction is cut off relatively early by rising costs in the case of curve type 7 (though not of type 6). Production must apparently stay at or near the least-cost point, regardless of cost or selling price, until the firm is forced out of business. Price changes are reflected directly and immediately in profit margins. This result, if borne out by further studies of this kind, rationalizes businessmen's antipathy to "chiseling," price-cutting, and "sales below cost" more easily than would the textbook world of U-shaped cost functions. But this is not antimarginalist. The conclusion, if valid, is as significant to a marginalist as to Eiteman, and equally conformable with his theory of cost.

M. BRONFENBRENNER*

[3] I refer to the use of terms like "slightly" and "gradually" in the descriptions. The divergence is actually quite marked for Eiteman's type 6 as he draws it. The drawing, however, appears to imply zero or negative marginal cost over part of the range, and the same is true of portions of certain other curves as drawn. Eiteman and Guthrie's arguments should not be judged on the basis of diagrammatic slips of this kind.

* The author is associate professor of economics at the University of Wisconsin.

Rejoinder

Rather than attempt a line-for-line reply to my critics, I shall try to meet the general purport of their comments.

First, it is pointed out that if the average cost curve starts curving upward even slightly, the marginal curve shoots upward rapidly, so that the conditions of marginal analysis are met by my curve No. 6. Mathematically this is true but businessmen do not know much about mathematics.[1] The description that accompanied curve No. 6 was intended to suggest a situation in which the least cost point was *so near* to capacity and the subsequent rise of average costs was *so slight* as to render the difference between curve 6 and 7 insignificant. In this respect the curve, as drawn, was deficient but discussion with a few businessmen who answered the questionnaire suggests that they interpreted the curve as I intended. If so, then the businessman who sets his

[1] Besides it should be borne in mind that the average cost curve is derived from the marginal cost curve rather than *vice versa*. That is to say, a marginal cost curve may rise slowly as capacity is approached; it does not have to rise rapidly. Those critics who howl so loudly at the omission of "overtime" (or beyond capacity outputs) had better consider the effect of slightly higher marginal costs of thousands of overtime products upon the average cost of millions of regular-production units, before venturing too far out on this theoretical limb.

scale of operations on the basis of inflowing orders and inventory limitations would ignore costs and would strive to expand production to the limit rather than to curtail output 1, 2, or 3 per cent short of the maximum.

Secondly, it is argued that all that marginal theory says is that business men seek to maximize profits. Unfortunately this is not all that marginal analysis implies, for the theory suggests also a technique for maximizing profits. It would be foolhardy to deny that businessmen desire maximum profits. My argument is that the techniques they employ do not work towards this goal even when their actual cost curve is U-shaped. Given a U-shaped cost curve and a relatively elastic average revenue curve, the most profitable point of operation is admittedly that scale of operations where marginal costs equals marginal revenue. However, in the world of reality, businessmen are not given "cost and revenue curves," and if they believe that their least cost point is at capacity when it is not, then the equilibrium point towards which they bend their productive efforts is capacity and not the point of equilibrium of conventional theory.

Thirdly, one critic admits that businessmen are not guided by considerations of marginal revenue and costs but he contends that the theory, when properly understood,[2] *explains* business behavior nevertheless. In those cases in which the "guiding principles" of businessmen happen to lead to the same result as conventional theory suggests, the explanation offered by conventional theory does not conflict with facts. However, in those cases in which the "guiding principles" of businessmen lead to a different result than conventional theory, the theory does not jibe with reality nor explain managerial behavior.

Furthermore, it must be remembered that theory is used to *predict* behavior as well as to explain it. For example, the question of the probable effect of a state income tax was raised recently in Michigan. The corporations said, "We will pass the tax on to the consumer in the form of higher prices"; a well-known economist said, "an income tax cannot be shifted."[3] Without entering into the merits of his argument, it will be recalled that the proposition that an income tax cannot be shifted rests upon an assumption that the sales price set by a manufacturer for his product is on the demand curve (it is the maximum price that could be charged for that quantity of the product). In theory no businessman would sell for less; in practice they do. It is dangerous to attempt to predict what businessmen will do by reasoning from theories that are based upon what businessmen do not do.[4]

In conclusion, the objective of an economist is not to draw pretty pictures

[2] A person who "does not understand" is obviously anyone who happens to comment on the discrepancy between theory and the facts of life.

[3] The president of one of America's largest corporations is convinced that his firm has always shifted the income tax to its customers.

[4] Marginalists seem to obtain a great deal of comfort from the fact that businessmen occasionally engage in marginal type thinking. For example, a firm manufacturing 9,500,000 products might weigh the cost of sufficient advertising to sell another 500,000 products against the profit to be obtained from the additional sales, before deciding upon the advertising expenditure. However, this is something quite different from setting prices and production schedules on such considerations.

on a black board suggestive of hourglasses, female figures and marginal theories, but to devise a theory (1) that *explains* and (2) that *aids in predicting* the behavior of businessmen under varying circumstances. In the area of current discussion this means explaining how prices are set and outputs determined in the short run.

Obviously the decisions of business managers who do these things are (1) arrived at without reference to principles or (2) based upon a body of principles. Kaplan admits that businessmen do not use his principles as guides. It is hard to believe that businessmen do not use any principles as guides. Therefore the proper procedure would seem to be: (1) to observe what businessmen do, (2) to reduce the observations to principles, and (3) to base predictions and explanations upon the application of these principles. Elsewhere I have suggested what might result from following such a procedure.[5]

One question remains: would the prices and outputs set by reasoning from principles that businessmen employ coincide with those that would result from an application of conventional theory? The answer is: occasionally yes but more frequently no. Hence my suggestion that "short-run price theory should be revised in the light of reality."

WILFORD J. EITEMAN*

Review of *The Economic Development of Poland:* Reply

Mr. Mandel's review of my book, *The Economic Development of Poland, 1919-1950* (the December 1952 number of this journal), was so unfair that a reply is necessary. His treatment of my handling of the interwar Jewish problem in Poland is particularly objectionable because he clearly implies that I was at least sympathetic with the anti-Semitism of that period. I should like to make it quite clear that any such implication is entirely unfounded. Mandel charges that, in my book, "Everybody, from the United States to Hitler and Stalin, is blamed for Poland's sorry plight, except the Poles themselves; but more than anybody else—the Jews" (p. 32). But on the page of my book to which he refers, I listed six different sets of circumstances which complicated the handling of the basic economic problems of interwar Poland; and the Jewish problem, one of the six, received no particular stress as compared with the other five. There is no basis whatever for the charge that I *blamed* the Jews for anything. What I did say, on page 103 (the other reference which Mandel gave), was:

> Some industries were almost completely dominated by Jews, for example, 94.7 per cent of the textile industry and 95.6 per cent of the leather and fur industry. The typical economic position of the Polish Jew was that of the small entrepreneur, and the concentration of two-thirds of the Jewish population within the cities presented a difficult problem in a country which had over 60 per cent of its total population engaged in agriculture, since the position of Jews in commerce and handicrafts blocked the natural channels of economic expansion of the non-Jew.

Mandel complains that I gave no reference for the figures cited. He failed to mention, however, that on page ix (which he cites), I explained that I lost in transit some of my research notes which contained the sources of these figures. He also failed to mention the supporting view of R. L. Buell (*Poland: Key to Europe*, London, 1939) which I quoted on page 104.

Mandel also takes exception to my treatment of "vast movements of population" (page 157), and says that while I decried bitterly the forced evacuation of a million Poles into Russia, I said nothing about "the three million Polish Jews driven from their homes into Hitler's extermination camps." Again the implication is that of sympathy with anti-Semitism. But my book was on the economic development of Poland, and I had no occasion to tell the complete story of the treatment of the Jewish people. And Mandel failed to mention that, on page 164, I quoted from a League of Nations report: "The rations of Jews amounted to half of the insufficient rations granted to Poles; and when the Jews were officially considered exterminated, no further issues of rationing cards were made to them."

J. Taylor

Rejoinder

1. Taylor heads his list of the obstacles to the solution of Poland's economic problems with "The economic aspects of the Jewish question." The fact that this one was listed first indicates to me that Taylor regarded it as the most important one of the six.

2. The real reason that I objected to Taylor's use of data (to support his view of the Jewish question) without sources was that, upon the basis of figures given in the last Polish prewar census (1931), I had very real doubts as to the correctness of his data. Nor am I impressed by the figures given by Buell.

3. I should think that the murder of three million Polish Jews was of as great economic significance for Poland as the removal of one million Poles (including 300,000 Jews) to Russia.

A. Mandel

MEMORIAL

Emanuel A. Goldenweiser

1883-1953

Emanuel A. Goldenweiser died at Princeton on March 31, 1953. For forty years Mr. Goldenweiser devoted his exceptional talents to the public service. His contribution to central banking thought, and particularly to the development of research in which he was a pioneer in the Federal Reserve System, cannot be measured. He was recognized and honored as a foremost economist, notably in the field of federal monetary policy. He will be remembered for those attributes which were so aptly described by the Reverend Mr. Bodo, pastor of the First Presbyterian Church of Princeton, New Jersey, in the memorial prayer at his funeral service:

> We thank Thee for the gentleness of his spirit which set the tone for all his relationships, within the family circle, among friends and associates, and in the wide reaches of his travels among men and nations. We thank Thee for his mellow, civilized wisdom and for his gracious sense of humor, quick to laugh but slow to judge.
>
> We are grateful to Thee, O God, for his enduring influence in the lives of his loved ones and friends; for his ability to communicate to others, humbly and informally, that integrity which shone through all his conversation and all his dealings; and for his devotion to young men whom he inspired with high ideals for the service of the Nation and the human race.
>
> We bless Thee, our Father, for his high regard of public trust and for his sensitivity to social and economic conditions which can do so much to enrich or to debase life, and for his constant responsiveness to human need, both near and far.

Born in Kiev in 1883, Mr. Goldenweiser spent his early life in Russia. After graduation from the First Kiev Gymnasium in 1902, Mr. Goldenweiser emigrated to the United States and entered Columbia University. He received a B.A. in 1903 and took an M.A. at Cornell University in 1905 and a Ph.D. in 1907. In the latter year he became a citizen of this country by naturalization.

His early studies and work were in the field of immigration, to which he was led by his special interest in Russian migration—the subject of his doctoral thesis—and by his concern for the human and social problems which this movement created. After receiving his degree, he served for three years as a research worker with the U.S. Immigration Commission. From 1910 to 1914 he was a special agent in the U. S. Census Bureau and from 1914 to 1919 a statistician in the office of farm management of the Department of Agriculture. In 1919 he entered the employ of the Federal Reserve Board as associate statistician and in 1925 became assistant director of Research and

Statistics. In 1926 he was appointed director of Research and Statistics and served in that position until 1945 when he became economic adviser to the Board. In 1946 he retired from the Federal Reserve and became a member of the Institute for Advanced Studies. He left the Institute in 1949 but remained in Princeton, studying, writing, and acting as a consultant on monetary and economic policy to, among others, the Committee for Economic Development.

Activities outside of the demanding duties of his work for the Federal Reserve Board were largely of a professional nature. He was active in the American Statistical Association and the American Economic Association, serving as president of the former in 1943 and of the latter in 1946. His contributions to cooperative efforts in coordinating governmental statistical and economic research activities were almost continuous, including membership in the Central Statistical Board and other interdepartmental groups. With a broad knowledge of world affairs and a versatility in languages, he was often called upon to participate in international conferences and was a member of the International Institute of Statistics.

Mr. Goldenweiser's published writings include "Immigrants in Cities" (Vols. 26 and 27 of *Reports of Immigration Commission*), 1909; (with L. E. Truesdell) "Farm Tenancy in the United States" (U. S. Census), 1924; "Federal Reserve System in Operation," 1925; two research studies for the Committee for Economic Development—"Monetary Management," 1949, and "American Monetary Policy," 1951; and numerous essays and articles. Among the last group, outstanding are his two addresses as president of the professional associations, some chapters in *Banking Studies*, published by the Federal Reserve Board in 1941, and "Jobs," the first of the series of *Postwar Economic Studies* published by the Board in 1945. It was largely, however, through unsigned articles in the *Federal Reserve Bulletin* and to a great extent through unpublished memoranda, off-the-record speeches, and just spontaneous comments that Mr. Goldenweiser made his greatest contributions to knowledge and understanding.

Mr. Goldenweiser made an outstanding contribution to the general recognition of the importance of economic analysis in government policy making. The progress of the Division of Research and Statistics and of economists generally throughout the Federal Reserve System is one institutional piece of evidence of this fact. His work in inspiring and assisting interdepartmental cooperation in the field of governmental statistics is another. He also played an important rôle in the establishment of the International Monetary Fund and the International Bank for Reconstruction and Development. One incidental by-product of the last was his successful insistence on the creation of the N.A.C. (National Advisory Council on International Monetary and Financial Problems) to coordinate U. S. international monetary and financial policy—today the outstanding example of effective interdepartmental cooperation in government policy formation.

RALPH A. YOUNG

BOOK REVIEWS

Economic Theory; General Economics

The Theory of Economic Policy in English Classical Political Economy. By LIONEL ROBBINS. (New York: St. Martin's Press. 1952. Pp. xii, 217. $3.00.)

This new book from the pen of Professor Robbins is a major event in contemporary economic literature. It touches upon the great issues of our science, and its treats of the towering figures from Hume to Mill who gave form and substance to economics.

Robbins' principal concern is the right interpretation of classical economics. The conventional picture of that era he finds distorted by the rise of a mythology that has turned the classical masters into caricatures—apologists of exploitation and opponents of social reform, who gloat over subsistence wages, care little for the welfare of the common people, and limit the government to the rôle of a night watchman. Robbins' aim is the restoration of the true picture of classical economics. This aim he pursues, in the main, by tracing the attitude of the classical economists on questions of public policy. The basic theme is introduced by a discussion of their view concerning the ends of economic activity and the system of organization most suitable for the realization of these ends. This is followed by a detailed appraisal of their theory of the economic function of government, and of their attitude toward popular welfare and collectivism. In the concluding chapter the classical movement is viewed as a whole from the wider perspective of the history of social philosophy.

Robbins' restoration of classical economics is a superb accomplishment. The picture which he unfolds on no more than 200 pages is far superior to the corresponding parts of the ordinary textbooks. His work is that of an analytical economist, and invites comparison with Cannan's masterpieces in its power of sustaining the argument in a systematic fashion.

How then does his argument run? The classical economists, he points out, considered consumption as the object of economic activity. With the end thus determined, they further held that it was best attained by means of a system of spontaneous cooperation. They are shown to have been public-spirited men rather than exponents of class interests. The harmony of interests which they claimed for their system was strictly limited. They were not indifferent to the fluctuations of trade, and in their speculations about money and credit they did not adhere to the belief in an automatic order that would not require regulation. Indeed, they recognized a substantial range of governmental functions, having been inspired by utilitarian empiricism rather than by the more dogmatic ideas of the physiocrats concerning a natural order. They did not view the system of economic freedom as a spontaneous or "natural" creation but as an artifact requiring conscious and sustained efforts to make it function properly. Interference with the working of the market

was conceived to be harmful only when the market conformed to their postulates. Interference with price or supply was accepted for public utilities and other monopolistic situations as well as in cases of special weakness of ordinary economic incentives. In the field of distribution, their works contain schemes proposing the drastic limitation of the inheritance of wealth. In the field of population, the gloom spread by Malthus' first *Essay* was dispelled by the possibility of improvement envisaged in subsequent editions. The classical economists recognized public functions in popular education and health care. They felt uneasy about the poor laws. Their works contain passages favoring restrictions on child labor and repeal of the anticombination laws. They did have misgivings about trade unions and collective action in general.

Having thus sketched the classical economists' system of economic freedom, Robbins goes on to explore their attitude toward socialism. Among the older generations of classical thinkers, from Hume to Senior, he finds only sporadic or implicit manifestations of attention to an issue which at their time was not fully joined. He refers to Hume's emphasis on private property and rejection of egalitarianism, to Smith's distrust of the central direction of economic activities, and to the similar views of Bentham; to Malthus' rejection of Godwin's egalitarian anarchism and of Owen's collectivism; to the critical attitude of the Ricardians toward Owen; and to Senior's verdict on the French revolution of 1848. Robbins then turns to John Stuart Mill, the only classical economist who concerned himself with socialism in a more systematic fashion. He interprets the apparent changes in Mill's attitude with profound understanding of Mill's complex character.

In his concluding appraisal of the general position of the classical group, Robbins emphasizes its character as a school of economic and social reform, which derived its prescriptions from utilitarianism and from a systematic body of scientific knowledge—the emerging science of political economy. Fundamentally, the utilitarianism of the classical economists was individualistic both with respect to means and to ends. It recognized, however, a substantial range of governmental functions as a prerequisite for the proper working of the individualistic organization of production. What then, and this is the last question posed by Robbins, was their view about the most desirable form of government? From Hume's philosophical conservatism the road leads to indifference in the youthful Bentham, later to give way to an appeal for representative democracy. To some this meant universal suffrage, and, while others pleaded for the maintenance of property qualifications, Mill came to favor a system of proportional representation combined with plural voting based on function and education. Robbins interprets this view as the expression "of an underlying anxiety, a scarcely suppressed fear: will the democratic society of the future have restraint enough to preserve the sacred liberty of the human spirit, and wisdom and self control enough to ensure its own progress and stability?—a momentous question to which, as yet, time has not given a convincing answer" (p. 205).

There is no need to elaborate further that content and form mark Robbins' book as a contribution of the first order to the history of economic ideas, a

field which has attracted only a few of the best minds among contemporary economists. It would be a difficult task to find an economist writing a prose more pleasing and persuasive than Robbins, and none combines a happier blend of urbanity and integrity. His present book, the product of lectures, has the inimitable charm of the direct address. Its value is enhanced by a wide selection of quotations from the original sources, by occasional references to an oral tradition now in danger of extinction, and by the light which it sheds on all but forgotten evidence on specific points (*e.g.*, the testimony of Pryme, cited on p. 121, which corroborates Bishop Otter in his preface to the second edition of Malthus' *Principles*). Also, the proper amount of attention is given to the economic ideas of Hume and Bentham, writers whose importance in the history of economic thought calls for more profound treatment than is usually accorded to them in secondary materials.

As Carl Menger pointed out over sixty years ago, the classical economists had the sad fate of having their history written by their opponents. Some thirty years later, Viner, in the sort of penetrating analysis for which he is famous, again established beyond all doubt that Adam Smith was not the doctrinaire advocate of *laisser faire* that he is so widely believed to have been. When all is said and done, one can but wonder at the persistence of a mythology which has been exploded at least once in every generation. The exploration of the factors which have contributed to so deeply rooted a misunderstanding might be an interesting task for a student of the sociology of knowledge. Let us hope that Robbins' work proves the definitive one, or, if it does not, that to the next generation of economists there will come again as civilized an appeal against an apparently perpetual wrong.

HENRY WILLIAM SPIEGEL

The Catholic University of America

The Rate of Interest and Other Essays. By JOAN ROBINSON. (New York and London: Macmillan. 1952. Pp. viii, 170. $2.00.)

The title of Mrs. Robinson's latest book is curiously modest since one of the "other essays" is entitled "The Generalization of the General Theory." Her main effort is to break through the short-run Marshallian confines of the *General Theory*. She frankly acknowledges her great debt to Harrod[1] and like him puts her faith in a marriage of the Keynesian statics with the classical dynamics. (From the present point of view it is irrelevant that he reads Ricardo while she reads Marx.) She has completed her long struggle of escape from Marshall. Her recognition of Kalecki as an independent discoverer of the *General Theory* is an overdue tribute from Cambridge to that distinguished economist.

Perhaps because of its scope and the difficulty of its subject matter, this book lacks the crisp lucidity of Joan Robinson's earlier work. That is one reason for the belatedness of this review. While one is continually impressed with her insight and shrewdness along the way, it is difficult to appraise the whole. In this review I shall attempt first to set out the various propositions

[1] R. F. Harrod, *Towards a Dynamic Economics* (London, 1949).

that she seeks to establish and then to make some comments on the work as a whole. In doing so, I shall take some liberties with the order in which she presents her ideas.

Her main theses, stated either directly or by implication, are:

1. Uninterrupted and steady economic growth is possible, but there are no economic forces at work that tend to establish it. On the contrary, the vicissitudes to which the economy is exposed would disturb the steady rate of growth even if it were achieved by accident.

2. These vicissitudes generate either booms or depressions. Booms continue till some "bottleneck" is reached. Depressions descend to a not too clearly defined floor.

3. The "business cycle" is a succession of responses to such vicissitudes rather than the result of a self-perpetuating tendency of a private-enterprise economy to fluctuate.

4. The rate of interest cannot be made to function as a regulator of economic activity that will ensure a steady rate of growth.

5. The course of innovation may affect the distribution of income in directions favorable to capital, or favorable to labor, or it may be neutral in its effects.

6. There is no especial virtue in a steady rate of growth. In particular, it may be associated with increasing unemployment.

Let us now consider these points in some detail.

1. The condition for a steady rate of growth is essentially the familiar Harrod-Domar requirement that the rate of growth of income or investment be appropriately related to the coefficient of capital requirements and the marginal propensity to save. In Harrod's terminology, $G_wC_r = S$, where G_w is the "warranted rate of growth," C_r denotes marginal capital requirements, and S is the marginal propensity to save, with technical progress assumed to be neutral.[2] This condition is simply an elaboration of the condition that for steady growth the normal increase in savings and the normal increase in investment must be equal.

The authors assume that the three factors involved are independent of each other and that if the steady growth of the economy is disturbed by some shock or irregularity there will set in a cumulative movement towards boom or depression with no tendency to return to the condition of steady growth.

Balanced growth must clearly require some degree of consistency among rate of growth, investment per unit of output, and saving. But to pin so much faith (or cynicism) on this particular formula is to go too far. In the first place, the formula is based on the modern revival of the old fashion of assuming "fixed coefficients"—which means throwing overboard the one important achievement of the neoclassical economics. Secondly, as Mrs. Robinson clearly recognizes, the concepts rate of growth and capital requirements are essentially vague. This vagueness is reflected in the statistical difficulties involved in their computation and is obscured by the precision with which the results are

[2] See *The Rate of Interest*, p. 93, and Harrod, *op. cit.*, Lecture 3, for full exposition of these conditions.

presented or discussed. If the analysis were presented with a clear recognition of the width of the confidence intervals surrounding the factors in the equation, it might create a very different impression.

2. I find Mrs. Robinson's discussion of "vicissitudes" one of the most useful and stimulating parts of the book. Her treatment of the supply of land has an attractive Ricardian ring—although she is concerned with the effect of land scarcity and rent on the Keynesian propensities rather than on the Ricardian wage-profit relation. She concludes her discussion of thriftiness with a welcome degree of scepticism about the existence of long-run tendencies toward under-consumption. Her discussion of population increase leads to the uncomfortable result that unemployment may result from rates of population increase that are too rapid or too slow. The discussion of finance, the emphasis on the distinction between finance and saving, and the relation between them are all valuable contributions to economic analysis. On the other hand, her de-emphasis of the price system is hard to get used to.

I am puzzled by the relation intended between Mrs. Robinson's list of vicissitudes and the booms and depressions they are supposed to explain. Most of the vicissitudes seem to be of the kind that would occur gradually over a long period of time. Yet they are essential elements in her explanation of the booms and depressions we associate with the business cycle. On the other hand, the notable exogenous disturbances, particularly wars and their aftermaths, which undoubtedly do produce booms and depressions, are not mentioned at all.

3. Mrs. Robinson is unsympathetic with attempts to establish the existence of business cycles. She states:[3]

> In those theories which purport to find a cyclical mechanism in a private enterprise economy, I have the impression that the weakest chapter is always the one which treats of revival from a depression. And it seems to me that this is no accident. I take leave to doubt (though with all due hesitation and reserve) whether there ever has been a trade *cycle*—that is, a self-perpetuating cyclical movement, as opposed to a series of fluctuations due to the propensity of a private enterprise economy to exaggerate its response, either way, to the chances and changes of history as it meets them.

Presumably, this point of view leads Mrs. Robinson to treat the third distinguished member of the Harrod family, Hicks' *Trade Cycle,* with scant attention. And while praising Kalecki, she pays no attention to his pioneer work in business cycle theory.

The lack of a theory of the mechanism of the business cycle leads Mrs. Robinson to the view that an expansionary vicissitude leads to a boom that ends in a bottleneck. A contractionary one leads to a depression (with limits not clearly defined). The only inkling of the mechanism of an expansion crisis and collapse we are given is contained in two short paragraphs:

> When the rate of investment rises relatively to what it has been in the recent past, consumption increases, in accordance with the short-period

[3] P. 142.

> marginal propensity to consume, and there is a secondary wave of investment in working capital, and a further increase in consumption. Now in some lines producers find themselves in a seller's market (demand exceeding capacity) and the optimists among them (or those with strong animal spirits) acting on the assumption that the demand will last, place orders for equipment to enlarge their capacity. So the upswing in investment amplifies itself.[4]
>
> At some point the rise in the rate of investment reaches a limit (we shall return to this point in a moment) and income reaches a maximum. Meanwhile new plants have begun to emerge from gestation; soon there is more capacity to cater for a rate of outlay that has ceased to rise. The sellers' market disappears (at best capacity only just catches up with demand—more often it overshoots the mark). The rate of investment therefore falls off, income declines, and the boom collapses.

The subsequent depression ends when something turns up:

> It seems to me that the most plausible theory of the revival is Mr. Micawber's: given time, something will turn up. That is to say that a depression will not last forever because some fresh opportunity for investment is bound to present itself sooner or later.[5]

With respect to bottlenecks, Mrs. Robinson rejects full employment, finance and land as ruling factors and concludes that industrial capacity is the crucial bottleneck. Her demonstration of this point is intuitively plausible but not logically convincing. She gives no compelling argument why resources cannot be shifted from increasing the output of consumers goods to increasing capacity—if capacity becomes short. If that can be done, the boom can continue so far as this particular bottleneck is concerned.

While I sympathize with Mrs. Robinson's aversion to an overformalized business cycle theory, I feel that her own discussion leaves far too much to be explained. I invite the reader to decide for himself how well her theory fits the facts of the last thirty years.

Mrs. Robinson is particularly concerned to demonstrate that interest rates will not serve as a stabilizer of the economy. First of all she emphasizes the point that will be widely accepted: that automatic adjustments of interest rates cannot be relied upon. While the process of inflation will raise the market rate if it happens to be below the full-employment rate, there is no effective mechanism to reduce a market rate that is higher than the full-employment rate. And deliberate action by governments to that end may do more harm than good if the authorities lose their nerve.

But even if the authorities do take action, the effects are likely to be less than is commonly supposed. Mrs. Robinson believes that we have been misled by our habit of thinking in terms of a single rate of interest. When the whole structure of rates is considered, she contends that increases are likely to be ineffective in controlling a boom. She reaches this conclusion largely as a result of including the yield on stocks as part of the complex of interest rates.

[4] Pp. 126, 127.

[5] P. 142.

(It will be remembered that Keynes in the *General Theory* included the yield on stocks in the marginal efficiency of capital side of the picture.) Mrs. Robinson argues that as an upswing progresses the yield on shares tends to fall, even though other interest rates increase. Consequently, businesses can raise capital on increasingly favorable terms so that the interest rate structure places no impediment in the way of a boom.

With the modern separation of management from ownership, the yield on shares undoubtedly bears some kinship to interest rates, and this should be recognized. On the other hand, the reason why the yield of shares declines in the upswing is simply that shares do represent an equity in the business and this distinguishes them from fixed interest-bearing obligations. The only adequate nomenclature is one which recognizes the equities as a separate category, to be identified neither with fixed interest contracts nor with investment in plant and equipment.

The existence of equities as a separate category probably does diminish the influence of increases in interest rates in checking a boom. But it need not eliminate that influence. The monetary measures that raise interest rates also render the yield on shares higher than they otherwise would be. There is no danger that monetary restriction will aggravate the boom.

The real point about monetary policy seems to be that, because of timidity or good judgment, the monetary authorities are unwilling to go far enough to stop booms or to cure depressions. But central bank operations on the scale required may have consequences that can only be discovered by experiments that no one is willing to undertake.

My concern with these major points prevents me from doing justice to Mrs. Robinson's elegant treatment of expectations and her interesting paradoxes such as "a rise in the rate of interest which is expected to be reversed is a greater deterrent to investment than one which is regarded as permanent."[6]

5. The chapter on the Economics of Technical Progress seems to me to be the least satisfactory in the book since it is almost entirely devoid of empirical content. The rest of the book is based on premises that the author believes to be true and which critics can attempt to refute. This chapter defines various categories of innovation and traces their economic consequences. But it makes no attempt to predict the kinds of innovation that will actually occur. While the definitions are useful and provocative, we are about as we were with respect to our knowledge of the effect of technical progress on the distribution of income. This is a field which I fear the theorist may have to yield to the historian.

6. The steady rate of growth as formulated by Mrs. Robinson or Harrod may be associated with increasing or decreasing unemployment and increasing or decreasing inequalities. Capitalistic development is governed by "fixed coefficients" which relates the behavior of the system as a whole to the character and extent of investment. And the nature of the growth itself is apparently uniquely determined, although not explained by Mrs. Robinson's system. She does not inquire whether public policy can achieve a steady rate

[6] P. 121.

of growth that is desirable in other respects. I surmise that she is too much of a Marxian merely to indulge in wishful thinking and not enough of one to accept the full implications of the deterministic position.

Apart from these comments on the positive aspects of Mrs. Robinson's theory, there are two general sins of omission to which special attention should be drawn.

In the first place, through her neglect of the relative price system, she may have neglected an important stabilizing influence in the economy. It is possible that the behavior of relative prices and the principle of substitution produce a tendency towards general equilibrium that holds fluctuations within reasonable bounds. The extraordinary stability that the American economy has shown since the war lends color to this view and leads to the hope that the depression of the 'thirties may not have been a normal occurrence of the later stages of capitalistic development. I have no desire to become labelled an anti-aggregator. We must think in terms of reasonably broad aggregates in order to think at all about major economic questions. But it is equally important to remember that we are dealing with nonhomogeneous aggregates whose behavior cannot be appraised unless we keep the workings of the relative price system not too far in the back of our minds.

Secondly, Mrs. Robinson does not discuss the central question of entrepreneurial motivation. Schumpeter, Keynes, Marx, and Marshall all provide theories, although conflicting ones, of what leads entrepreneurs to invest or innovate. Mrs. Robinson (and Harrod) merely provide a mechanism and do not tell us what determines how hard the entrepreneurial foot is pressed on the accelerator. While theories of entrepreneurship are eminently unsatisfactory, I do not see how we can escape the need to select the hypothesis that is least likely to be wrong or which will lead to the least undesirable consequence if it is wrong.

I confess that I conclude this review with a less sympathetic view of Harrodian dynamics than I had when I began it. The three protagonists, Harrod, Hicks, and Robinson, with essentially the same tools of analysis, reach widely differing results. Harrod finds a chronic tendency to underconsumption. Hicks discovers at the end of his book that the real trouble is monetary and that if policy could confine fluctuations to his "real" cycle all would be well. Mrs. Robinson paints an agnostic picture of capitalistic instability. While they all deserve great credit for recentering attention on economic growth, the *General Theory* has not yet been successfully generalized.

ARTHUR SMITHIES

Harvard University

Die Theorie der Einkommensverteilung. Entwicklung und heutiger Stand. By VIKTOR ZARNOWITZ. (Tübingen: J. C. B. Mohr (Paul Siebeck). 1951. Pp. 275.)

The history of economic doctrines, as a method of training economists and as a subject of study, has declined in relative importance during recent

decades. This is an almost inevitable consequence of the rapid growth of economics as a specialized science, but it has probably meant some loss in perspective. Moreover, it may be argued that the writing of doctrinal history is a task for mature economists with long working knowledge of their special fields, rather than for a young man. Dr. Zarnowitz attempted a survey of the theory of distribution as a doctoral thesis. But although he may wish to rewrite (and shorten) it in twenty years' time, he has done a useful service, particularly to the German-speaking economist, in presenting and analyzing German as well as recent Anglo-American contributions to the subject which cannot be well-known in Germany. The older classical theories of distribution are dealt with rather cursorily, and the book really begins with the theory of imputation developed mainly by the Austrian school of economists, which shades over, however, into the modern theory of marginal productivity. The conceptual framework of this theory is analyzed in much detail, both in its micro-economic applications for conditions of perfect and monopolistic competition, and as a method for determining the share of factors in the national dividend. The partial analysis follows familiar lines and is undoubtedly competently done. The author takes, on the whole, the position which Machlup had developed in his criticism of Lester's empirical studies. It certainly makes the logic of micro-economic theory of marginal productivity unassailable, but does it not destroy at the same time its scientific character, by making verification well-nigh impossible?

The determination of absolute and relative factor shares runs into heavy weather as soon as the classical assumptions of perfect competition and full employment are relaxed. The author is fully aware of the difficulties and stresses the need for further work, particularly on the special factors influencing the price formation of factors of production. He analyzes, for instance, in connection with Oppenheimer's theory of the agricultural frontier, the importance of the unequal distribution of wealth for the supply conditions of the labor market and the tendency for given distributions to reproduce themselves. There are interesting discussions about different distributional principles in different economic systems, but this last part of the book is on the whole less rigorous and less well-planned than the earlier chapters, and could be omitted without much loss. It would be wrong to hold this against the author, who has certainly proved his competence and skill in the field of distributional theory.

Oxford University

Unternehmergewinn und Arbeitslohn. By Erich Carell. (München: Richard Pflaum Verlag. 1950. Pp. 176. DM 19.50.)

Professor Carell, like many other economists, is dissatisfied with the development of the theory of profit since Marshall, and turns in particular against numerous attempts to explain profits as a residual income imputable, say, to entrepreneurial ability. The premature introduction of subjective factors in his view undermines the objective basis of such fundamental con-

cepts as the optimum size of the firm, or the optimum combination of factors, and hence the very notion of equilibrium. Profit is not the reward for a factor of production, be it risk or entrepreneurship or management. Payments for risk taking, interest on capital, or rent, and for management, are rightly included in the average cost curve. Profits (*Unternehmergewinn*) can only arise through objective economic changes, and the change the author considers at length is the gradual introduction of technical innovations. The analysis assumes perfect competition, price flexibility and mobility, and is conducted in terms of comparative statics. When the system is in equilibrium, all firms within an industry will use the same factor combination and be of equal size. Excess profits will be zero for all firms. Assuming neutral money, technical progress will secure differential profits for the pioneers which will, however, be matched precisely by losses of other firms, so that profits for the economy as a whole in these "dynamic conditions" are again zero. Loss firms will not fully recover their depreciation allowances but the differential profits of the pioneer firms will be enough to keep aggregate capital intact in money terms. Prices will, of course, fall with the increase in output associated with technical improvements. Real factor incomes will rise and so will purchasing power of capital that has been maintained constant in money terms. There will be neither over-employment nor under-employment throughout the process of adjustment. Marginal producers will continue as long as they cover variable cost, and loss firms can only introduce new machinery when their depreciation allowances, augmented by differential profits of other firms, are sufficient to enable them to buy new equipment. As technical improvements spread to other firms prices will fall further, and the system will come to rest only when all firms are working again with the best technique and all profit differentials have been wiped out.

Given the explicit and implicit assumptions of this model, most of the deductions seem to follow logically. In fact so perfect appears the working of this simplified model that Carell uses it as a norm for economic policy. If, for instance, a policy of neutral money is abandoned and technical improvements are accompanied by credit expansion designed to keep prices stable, real wages will fall, higher profits will accrue to the pioneers, while marginal producers will not make losses. On the stringent assumptions of the model this is, of course, a *non sequitur* since credit expansion will simultaneously affect commodity prices and factor prices and hence inflict losses on the marginal producers. The assumption of a sluggish response of wage rates to monetary expansion in a situation of full employment may or may not be realistic, but it seems to introduce time lags which otherwise are consistently kept out of the system.

Carell is, of course, in good company when he uses his simple logical system as a stick to beat all the sinners of the real world: monopolistic practices, government interference, credit policy, and so forth. But it might have been more instructive if he had relaxed some of his over-simplified assumptions and investigated, for instance, technical improvements requiring more capital per head, or capital-saving inventions, or the effects of varying rates of innovations on the system as a whole, or the impact of innovations in conditions

of underemployment. His analytical base seems to the reviewer to be too narrow to carry the policy implications which are drawn from it.

FRANK BURCHARDT

Institute of Statistics
Oxford University

Dimensions de l'homme et science économique. By JEAN-LOUIS FYOT. (Paris: Presses Universitaires de France. 1952. Pp. 355. 1400 fr.)

The volume under review is one of a series of publications issued under the auspices of the Bibliotheque de Philosophie Contemporaine of Paris, France. The numerous publications of the Bibliotheque appear to fall into the following categories or sections: Psychologie et Sociologie, Historie de la Philosophie Generale, Morale et Valeurs, and Logique et Philosophie des Sciences, in which last category Fyot's contribution takes an honored place.

In a delightfully written preface Fyot informs his readers that Aspects of Man and Economic Science (free translation of the French title) is not a review of historical economic thinking but rather an examination of contemporary political economy. He proposes to deal only with problems which have continually faced mankind regardless of whether or not these problems have been examined in scientific studies. His justification for this position is that contemporary problems embody problems universal in time and therefore their treatment does not require a review of various economic schools.

Following the Preface comes a lengthy Introduction in which he considers what he deems to be the two chief phases of economic thought, liberal individualism and the socialism of Marx. He pays his respects to the Physiocrats, yet holds that it is with Adam Smith and J. B. Say that political economy finds itself promoted to the rank of an exact science. Passing to Karl Marx he asserts that Marx pretended to erect a science of economics which would at the same time be a philosophy of man but wound up by working out an economic system which absolutely contradicts man's aspirations.

By far the major part of the volume is devoted to the social, individual and human aspects of man and economic science. In Part I, under the head of The Social Aspect, he notes the underlying relations between producers and consumers, stressing the reciprocal dependence of economic functions and the solidarity existing between producers and consumers. Toward the end of this part he takes up theories of general equilibrium and disequilibrium and concludes with a thoughtful study of the interdependence of nations.

Part II, entitled The Individual Aspect, begins with an account of the economic calculations and behavior of individuals, discusses the planning procedures between which entrepreneurs must choose, goes at length into the topics of private and national saving and investment, and ends with a presentation of the difficulties posed by international economic fluctuations.

In Part III, where the author deals with The Human Aspect, he feels constrained to remark that the concrete limits of political economy, as a science, are at bottom those of the economic subject himself within his objective mani-

festations. Here we run into the insuperable difficulty that there is no rule of conduct to which man conforms. He refuses to act in accordance with the dictates of reason. Since both the agents and the ends of economic research are concerned with human behavior, he further maintains, all hope that political economy can ever become an exact science must be abandoned. Economic laws, as rules of conduct, can never pretend to come to the exactness, for example, now approached in the laws of the physical and chemical sciences. Like the moral or juridical sciences in which man's behavior constitutes the center of research, political economy is thus by its very nature a normative study. Incapable of satisfying to the full his individual and social aspirations man is perforce obliged, under penalty of violating the laws of human conduct, to pursue incessantly an ideal which he knows is inaccessible.

Is there accordingly no answer to the enigma of man's destiny? This question remains without an answer, he replies, unless the answer is found in the love of God. The existence of a God who is Love, and whose love provides the same bond between man and man and between man and nature as between man and God, guarantees by His transcendence no less than by His eminence the worth of efforts undertaken to promote, here below, the demands of love inscribed in the hearts of human beings, of which demands economics has revealed to us one phase. Is not the love of God, he concludes, the ultimate question with which the economist and the philosopher ought to concern themselves in their research?

The subtle and elusive rôle which normative concepts and ethical preconceptions have played in economic thought from antiquity to the present time is a rôle that has long enlisted the attention of not a few gifted thinkers. No volume has come to my notice which attempts with greater care the extremely difficult task of treating all the social sciences as inevitably ethical in content and character. That Fyot's deft analysis is by no means the final answer, in my opinion, to the issues which he has raised is in no way a reflection upon the artistry with which he has endeavored to resolve a problem which is possibly unresolvable. Thoroughly documented, with evidence throughout of a broad and sympathetic understanding of economic literature, and written with typical Gallic charm, his book is an admirable example of the emphasis which should rightly be laid upon the human aims of the economic system, an emphasis, incidentally, with which few will quarrel.

John M. Ferguson

University of Pittsburgh

An Introduction to Economic Analysis. By J. K. Eastham. (London: English Universities Press, Ltd. 1950. Pp. vii, 392. 15*s.*)

A Course in Applied Economics. By E. H. Phelps Brown. (London: Sir Isaac Pitman & Sons, Ltd. 1951. Pp. viii, 434. $5.75.)

The writing of textbooks in elementary economics seems at times to be a rather distinguished form of "disguised unemployment." There is practically no marginal social net product, and one would guess, very little of the private.

Freshness of material, novelty of approach, and distinction of style are missing, and about all that is done is to change the chapter order, and to substitute 1952 data for 1951 data so that the publishers can proclaim that their offerings are "timely." But books such as the two here reviewed cannot be dismissed on these terms. They are new; they have been written because their authors felt that they would meet a need not now recognized; they are clear; and without doubt they are both useful. Neither may serve adequately as one of the books to be given to beginning students, but both deserve careful consideration. And for American use each can be strongly recommended for certain courses above the elementary level.

Mr. Eastham's *Introduction* packs into a relatively small space (about 400 pages) a great deal of what goes by the name of economic theory, at both the micro- and macro-economic level. By this I mean that it introduces the reader to most of the economist's tools of analysis—to indifference curves, the marginal productivity function, to the marginal revenue when a monopoly discriminates, the marginal propensity to consume, and many others. What it does not do, and for many this will prove a serious omission when they consider adopting the book for an elementary course, is to show the uses to which these analytical tools can be put. It is a book about economic theory rather than about an economy. And for this reason it is difficult without being, at the same time, rewarding—at least for use in this country. It would be a valuable reference book for students who have gone well beyond the introductory course and who have got the feeling of what economics is all about, but to use it at the beginning level would mean deadening the interest of most students, and giving to the rest a false picture of the subject. Despite this, it is a distinguished book which, though it fails in its announced aim (for the American beginner, anyway), rarely says a wrong thing. (But is it true that the rejection of Say's law depends mainly upon the fact that the process of supply is not instantaneous?) It could be studied very profitably by anyone who, finishing his undergraduate work, wanted a bird's-eye view of what he had learned.

Professor Phelps Brown's *A Course in Applied Economics* is, as the title suggests, in some ways at the opposite pole. It has not been written to set out analytical tools; instead its function is to show how they can be used. The reader is presumed to have studied theory and he is in this book brought up against "real" problems and shown how analysis mixed with judgment can provide solutions. The problems with which it deals are wisely chosen so that most aspects of the functioning of an economy are considered. The working of the pricing mechanism is carefully examined not in the abstract but by dealing with such problems as the formulation of policy for monopoly, and the pricing policy to be followed by nationalized industries. This whole treatment is unusually clear and yet brings out what economists would like their students to learn—that the answers are not likely to be found in simple slogans. In addition, problems of income stabilization and international trade are considered. Here again the treatment is excellent. This book deserves a place somewhere in the curriculum for it paints a very clear picture of how economists work. It could be used successfully as a supplement to an intro-

ductory text which presents basic theory, though it would probably prove even more valuable at a subsequent stage. While it is concerned with the problems of the British economy, this should not, I believe, reduce its value in this country.

LORIE TARSHIS

Stanford University

Economic History; National Economies; Economic Development

Enterprise and Secular Change—Readings in Economic History. Edited by FREDERIC C. LANE and JELLE C. RIEMERSMA. (Homewood, Ill.: Richard D. Irwin, for the American Economic Association and the Economic History Association. 1953. Pp. xi, 556.)

There are good reasons for feeling well disposed towards this volume of readings in economic history. Its appearance suggests that economic history is no less alive and worthy of consideration than price theory or the theory of international trade—he who comes last is not necessarily least; and a volume which is the result of collaboration between the American Economic Association and the Economic History Association must make a strong appeal to all those who value progress in both economics and economic history and who believe that contact between them can lead only to the enrichment of both.

Within the covers there lies—as was said about a sheep's head, although Professor Gay has it that it was a haggis—some "fine, confused feeding." The volume is divided into three sections: the first dealing with Business Units; the second with Money and Prices; and the third with Method. Each of these sections contains some excellent articles (or selections from published work): one remembers especially the brilliant contributions by Gay, Heckscher, Mitchell, Nef, Sombart, Spiethoff and J. H. Williams. The variety is very great with respect to period, location and subject matter; from the Italian Cities of the Renaissance to the Growth of the Large Corporation in America, from the monetary theories and policies of Gustavus Vasa to Ricardo and the Bullion Report. There is writing by scholars from six countries, dating from 1890 to 1949. Of course the selection will appear ideal to hardly any reader, perhaps to no reader; and it would be easy—too easy—to reel off a list of names which one might have expected to find included but does not. What strikes one first, and what matters far more, is the range and variety of the contents.

Thus Section I begins with a series of excerpts from Schmoller and ends with Cole's "Approach to the Study of Entrepreneurship"; Section II begins with Wesley Mitchell's stimulating "The Role of Money in Economic History" and ends with John H. Williams on "The Crisis of the Gold Standard." But as the reader reaches this point he begins to wonder what principles have dictated the choice of articles. Is the book really as orderly as the division into sections would make it appear? It would not be claimed, surely, that each of these articles in the first two sections is the best available on its subject, having regard to the state of knowledge and opinion in 1953; nor are all of them rare articles, difficult of access (although admittedly five

of the twenty-one essays in the first two sections are translated for the first time into English); nor could all of them be regarded as path-breaking contributions to economic history. There is, it is true, some sense of unity, especially in Section I which emphasizes the centuries-long importance of the man of business in the western world and illustrates, besides, the long process of building up and breaking down theories of "economic stages." But articles on so many themes, by so many different hands, coming from so many countries and originating in so many points of view must present rather a disorderly appearance, must leave the reader wondering what economic history is about and what its practitioners would be at—and this is true even of the reader who thought that he knew the answers to these questions before he opened the book.

It is, however, here that the editors, possibly foreseeing this troubled state of mind, cunningly insert their section on Method: one article each by Gay, Clapham, Heckscher, Spiethoff, Simiand and Bloch. Of these articles, three appear in an English translation for the first time. This section is rather like the last volume of *À la recherche du temps perdu:* it resolves, or at least partially resolves, a number of doubts and problems. It focuses attention on the two grand questions: What is the purpose of studying economic history? What (even more insistently one finds oneself asking this question, prompted by the whole idea of the book)—what is the relationship of economic history to economic theory?

Few economists or economic historians can be happy about present-day relationships between economic theory and economic history. These two aspects of what might be supposed a unified discipline too often seem extraordinarily dissimilar. In the work of Marshall (himself, as Schumpeter, reminds us, an economic historian of the first rank) theory and history went hand in hand; but in whose *Principles* since Marshall's does history find an integral place? There seem to be two reasons for this alienation of history from economics. First of all, the years between 1890 and 1940 or thereabouts saw economists increasingly concerned with the study of equilibrium positions; and economic equilibrium is not an historical concept. Secondly, economists have recently become increasingly concerned with prediction. Now in prediction only short time periods can as a rule be considered, because demand changes, technological changes and political or social changes have to be eliminated as uncertainties. It is not true that they are not certain because not man-controlled, but they are simply regarded as beyond the convenient limits of the system. Therefore it is in a sense true to say that if economics is to be a system capable of prediction it must be a short-run economics. (And of course it is open to anyone to suggest that attempts to construct a systematic view may lead to the advocacy of a systematic economy into which change enters only at a controlled rate. Whether this is either possible or desirable is, however, an altogether separate question.)

Fortunately, there has been a reversal of the first of these trends in the last ten or fifteen years. Economists are now increasingly interested in problems of change and uncertainty, and with respect to these the study of economic history should be of the greatest importance. (The problem of entrepreneurial

here we return to the problem implicitly posed by the volume before us; even when economic history is not mere "total immersion in a bath of appearances" it can still be anything from *Der Moderne Kapitalismus* through Heckscher's "Natural and Money Economy" to Williams' "The Crisis of the Gold Standard." Are all these styles of thinking equally valuable and equally suited to effecting a reconciliation with economic theory?

Enterprise and Secular Change seems to suggest that there are three kinds of economic history. There is economic history simply for the sake of knowledge—for Light, in Pigou's phrase, not for Heat (although the difficulty here is that all knowledge, as Collingwood emphasized, must be organized in some way, and it is not always clear in what way this kind of knowledge is being organized); there is economic *Gestalt* theory, for both Light and Heat; and there is economic-historical classification and generalization for, in the opinion of the present reviewer, neither Light nor Heat. Each of these types has its practitioners and supporters. (A particular regret about the choice of articles, this time too keen to be suppressed, is that the editors, while giving us Spiethoff's own analysis of economic *Gestalt* theory, did not also give us a specimen of it by abstracting some passage from *Krisen.*) The relationship of the first and last of these types of thinking with analytical economics is unlikely to be either close or constructive; hope (for those of us who do hope for these things) lies chiefly in economic *Gestalt* theory of some sort. And here, it would seem, the economic historian may re-form the theorist's picture by stressing the shifting motives, the varying underlying social forces, the factors influencing demand and supply in the long run, the extraordinary complexity of the "real" world (as in Nef's masterly analysis of capitalism in France and England between 1540 and 1640, where not a few of our modern "discoveries" or rediscoveries about the inflationary process are anticipated). Thus the study of economic history should help to make the assumptions from which theory begins as reasonable for each environment and as clearly stated as possible.

Whether it was the intention of the editors of this book to provoke thoughts such as these is not clear; they seem, to judge by the Preface, to have had rather too many aims for comfort, and one trembles to think what the effect of the book might easily be upon "young scholars starting upon their own investigations" (p.v.), for whom, it is suggested, the book is suitable. But there can be few established economic historians or economists whose economic view will not be widened by reading this volume and reflecting upon their own work in the light of the conclusions which it helps them to reach; for it stimulates and provokes as well as enlightens. It reveals a handsome part of the great spectrum of economic history; it should stimulate us to fresh enterprise of our own, undertaken with a sharpened sense of purpose.

One last word. May we hope that those responsible for *Enterprise and Secular Change* will think now of a second but slightly different volume, *A Survey of Contemporary Economic History* or—to paraphrase another and an older title—*Essays on Some Unsettled Questions of Economic History?*

A. J. YOUNGSON BROWN

Cambridge, England

Winchester, The Gun that Won the West. By HAROLD F. WILLIAMSON. (Washington: Combat Forces Press. 1952. Pp. xvi, 454. $10.00.)

Students of American economic development can readily agree with the author's statement that "Understanding of this period of American history is still incomplete." Hitherto, the stress has been mainly on our abundant natural resources, the phenomenal development of technology, the rapid increase of population, laws and decisions of courts, and so forth. Such accounts are barren when it comes to an understanding of the dynamics of our development. The invisible, intangible operating forces have been neglected, including such factors as individual initiative, imagination, vision of the future, "drive," and willingness to take risks. In this volume, with reference to the Winchester enterprises, the author supplies the necessary elements. He presents not only the development of the arms industry, but the capacities and personalities of leaders in this business.

The account covers the period from about 1855, when Oliver Winchester the founder, became interested in firearms, to about 1932 when the Winchester organization became an important part of the Olin industries. For men who could see them, opportunities lay before the eyes of prospective producers of arms. For one thing, fabricators abroad did not understand the requirements of users in this country. What worked for small game hunting did not work for large wild animals, and when the purpose was to fight Indians a gun that discharged one bullet and had to take time out for reloading was not much protection against charging Red Men. Moreover, expert riflemen were punctilious in their choice of guns. With us firearms had to be adjusted to the individual requirements of the users.

The author indicates that a small domestic industry began to appear in America in late colonial times, helped along by immigrant artisans from Germany and Switzerland. The advent of Eli Whitney, the inventor of the system of interchangeable parts, contributed an advantage to workers in this country. Oliver Winchester was not a pioneer in this industry, but he helped to prepare the way for better methods of production and for new types of arms. Prior to his entrance into the arms business he was a merchant selling men's furnishings. The author described him as "a new type of entrepreneur in the fire-arm industry." His predecessors in this business were inventors and skilled mechanics. In our history a shift of objective was not unusual, as was the case with Eli Whitney who was destined for school teaching, but through a chance remark of a friend, was directed to the invention of the cotton gin. What Winchester lacked in mechanical ability was more than compensated by his ability as a salesman, his grasp of financial matters, and his choice of subordinates who could advise him on technical matters.

An important feature of this book is the manner in which the author discusses policy questions which beset the Winchester management. In a growing country business conditions were in continuous flux. An unending task confronted managers in adjusting to new conditions. With Winchester, various questions were always to the fore: How to meet competition, whether to stick to traditional lines of production or to branch into others, and in such

case what others should be added to sustain profitable levels in the whole undertaking. Also, there were employment policy questions such as whether to use a contract system among employees or the standard daily wage. Should the company manufacture hardware which had little or no connection with its main lines? How should goods be sold—by direct sale to retailers, through jobbers, or through a chain store system, as was once considered?

In the period shortly after the Civil War the company encountered a new class of problems. This was the era of the beginning of combinations, trusts, trade agreements and, of course, laws against these practices. The management had to decide what course to take. It did engage in some of these practices. Problems existed in other fields, as with government contracts, and with policies for developing domestic and foreign trade. As yet, modern advertising was still in the embryonic stage, but more or less crude methods existed to call attention to the virtues of a company's products. It maintained a group of field representatives such as salesmen, "missionaries," and shooters. The duty of "missionaries" was to distribute posters and hangers to display in shops and windows, along with envelopes and order blanks. The shooters played the dramatic rôle—they were the experts who demonstrated the virtues of Winchester guns. The prestige of the company was further increased by testimonials of well-known riflemen. Finally, towards the end of the company's career the critical question was how to keep the organization afloat in face of losses.

These are merely a sample of the many questions to which the owners had to find answers. In short, this book is much more than a narrative of the company's growth. In a measure, it is a useful case study on business management as applied to this organization. The book is supplied with an extensive bibliography, and illustrated throughout with types of guns and various accessories used by the company.

Washington University

Economic Development of the United States. By John R. Craf. (New York: McGraw-Hill. 1952. Pp. vi, 598. $5.00.)

This volume deals with the economic development of the United States, presumably at the level of the beginning college student. In a field as rich in "facts" as that of the historical growth of the highly complex American economic society, a textbook author assumes the task of identifying those elements of the story which, when related in coherent and meaningful fashion, will constitute not only a solid foundation for the student's understanding of the nature of economic change but also for a more abstract analysis of the whole (theory), and for more detailed examinations of the rôle of the major institutional components. The task requires a purposeful organization which supplies the criteria for selecting the data to be discussed, and which leads to and supports reasonably explicit conclusions. Detail enriches or confuses, depending upon the skill with which the relevance of individual facts to a larger whole is indicated.

In this volume there are few hints to the student as to what is significant, or why, and numerous occasions for mental indigestion. We are told that "The general theme of the book is that the United States began as an agricultural nation and remained within that category for more than two hundred and fifty years. . . . In time settlers were followed by organized governments, transportation agencies, merchants, bankers and farmers. These became the nucleus of a highly developed society. As urban centers arose and as the United States matured, the threads of industrialization brought major changes to the pattern of American economic life. Slowly at first, and then at an accelerated pace, transportation and industry became essential in the economic structure." What is said about the agricultural nature of American society suggests a possibly fruitful interpretative approach to the subject-matter. Unfortunately, one looks in vain for either outright statement or indirect suggestion which develops this point of view. If the rest of the quotation can be said to suggest a theme, nowhere in the volume is it developed as such.

Few professors have escaped the experience of being approached by one of their students with the question: "How much of the detail in the text will we be held responsible for?" Such questions are usually and justifiably shrugged off with a stock answer. The query may, however, also be a source of embarrassment since it may legitimately arise from the failure of the instructor, or the textbook employed to perform the essential teaching task of supplying the organization, and suggesting interpretations and value guide lines, which help the student in developing his own capacity to judge as to the significance of data. Without such a set of interpretative tools, students (and the instructor) are lost in a wilderness of assorted, unclassified, unappraised "facts." The instructor using this volume will have little assistance in helping his students find their way out of the dense forest into which they have been led.

CLARENCE H. DANHOF

Washington, D.C.

A Short History of the International Economy, 1850-1950. By WILLIAM ASHWORTH. (New York and London: Longmans, Green. 1952. Pp. 256. $3.25.)

A well-written textbook which does more than rehash conventional materials deserves more than perfunctory notice. Professor Ashworth, a lecturer in economic history at the London School, has compressed into 250 pages the substance of a course in the history of international economic relations since 1850. The work aims to meet the needs of university students, but the author hopes it will "be of some value to the general reader with a lively interest in the process of historical development and the nature of modern society." Both purposes have been well served.

International, Ashworth observes, means "common to many nations" as well as "between nations." Although he deals with international phenomena in both senses, the emphasis centers on the processes of change and growth common to two or more countries. Breaking away from "certain current

fashions in the writing of economic history," he eschews "detailed consecutive treatment of the internal economic history of particular countries."

The story begins in the mid-nineteenth century, when "there were clear signs of change in progress and greater change impending." This seems strained; for "signs of change in progress" must have been as readily observable in 1846, or 1861, as in 1850. Though it is difficult to establish landmarks in economic history, probably the beginning of England's half-century under free trade qualifies as a convenient point of departure. Certainly, it added significance to international intercourse.

But the expansion of trade and the migration of British capital were not the only channels through which an international economy emerged. Prior to 1914, the spread of mechanization, resulting in "a massive expansion of primary production," reached manufacturing, mining, transport, and even agriculture universally. "Yet, though mechanical techniques became dominant in the economic activity of the world as a whole, they did not spread to every occupation or to every place." In eastern Europe traditional methods of farming, "too often a euphemism for semi-starvation," persisted; and colonial governments in the Far East restrained the development of industries which competed with imports from the home country. We lack extensive cross-sectional data, or long time-series, for more than a limited number of countries; but Ashworth presents a trenchant verbal analysis of the uneven flow of technology and machinery into the national economies of the East and the West.

More or less common experiences with the factory system, scientific management, business organization, and concentration accompanied the mechanization of production. While there were "numerous exceptions to the increase of business concentration," they were "too few to diminish the significance of the general trend." The labor movement, too, took on many international characteristics; although, "when tested by the First World War, patriotism proved far stronger than industrial solidarity."

Looking at "Government and Economic Life," Ashworth finds that no European country ever "came so near to laissez-faire as Britain"; but American philosophy, except for the high tariff, "carried laissez-faire further than it ever went anywhere else." Nevertheless, government regulation, economic planning, and public ownership widened their beachheads in every national economy. The differences were differences of timing, methods of control, and areas of intervention.

The "emergence of an international economy" resulted from the diffusion of technology and tools and the mass migration of people across national boundaries. Surely, there were earlier signs of its emergence—even in the sixteenth century—but the increasing interdependence of nations sharpened the contrasts between the nineteenth and earlier centuries. "Hardly any part of the world was permitted to remain economically self-contained, and the course of economic activity in any region tended in consequence to become more dependent on events and decisions in other places."

The outbreak of war showed "just how delicately balanced was the international economic system"; and the developments of the ensuing thirty-five

years repeatedly halted the prewar tendencies for the international economy to expand. Fresh attempts to enlarge the area of international division of labor often ended with agreements to curtail production, limit migration, and insulate national economies from the international. In contrast with the generally beneficent changes underway at the middle of the nineteenth century, the "signs of change in progress" in 1950 seemed to portend the continued disruption, contraction, and fragmentation of the international economic order.

This sane and carefully constructed account of a century of economic development yields little by way of conclusion or recommendation for reform. Ashworth has fulfilled his promise to show how "the bright promise bestowed by a century of material achievement was clouded by doubts whether the achievement might not be turned to base uses or utterly destroyed." The evidence strengthens the conviction that "the creation of an international economy" remains, as it was in prewar years, "the necessary accompaniment of the rapid development of the world's wealth, a process . . . almost universally regarded as beneficial." But when merely economic remedies for economic problems become unpalatable or seem impractical to those wielding political power, the counsels of an economic historian lose their charm.

ROBERT S. SMITH

Duke University

Soviet Economic Institutions—The Social Structure of Production Units. By ALEXANDER VUCINICH. (Stanford: Stanford University Press. 1952. Pp. x, 150. $1.75.)

Two aspects of the social organization of production units—power relations and group differentiation—are the main foci of investigation in this little book. In the study of power, defined as decision-making, the book examines the rôles of various groups viewed first in terms of their functions (managerial, control and social mobilization) and secondly in terms of their organizational form (government, party, trade union, "voluntary" organizations.) The study of group differentiation deals primarily with social stratification and mobility. Both problems are investigated successively in each of the five production units: the factory, collective farm, state farm, machine and tractor station and industrial cooperative.

Each production unit is treated separately, and the author leaves to the reader the task of generalizing from the material presented in each case. This, coupled with the numerous qualifications which are inevitable and commendable in the study of institutions so complex and so full of contradictions, makes it difficult to pick out the main theses. The following two points, however, are among the most prominent: (a) Power is lodged formally in the manager of the factory and the general meeting of the collective farm, but the incursions made upon this power by government and party organizations have diluted it to the extent that the manager is reduced to a mere "bureaucrat serving as a direct link between an economic unit and the government bodies," and " 'kolkhoz democracy' . . has shrunk to insignificance before the continually expanding network of channels devised to subordinate the

countryside to an indisputable authority of central government and Party quarters." (b) Within production units planned increase of social stratification has resulted in the "consolidation of the intelligentsia as a well-delineated status group," greater status differentiation among workers and peasants, and reduced mobility within and between status groups. There is nothing new in these conclusions, but it is in the qualifications and amplifications that the author makes some interesting contributions; for example, the "informal organization" by means of which factory management reacts to government and party incursions upon its power.

The author is severely handicapped by lack of space. Fifty-one pages are devoted to the factory, 42 to the collective farm, and 39 to the other three organizations. A substantial amount of this space is devoted to a highly condensed presentation of historical and descriptive background information, which leaves little room for a full development of the main arguments. Consequently, the implications of some of the more interesting observations are not explored. For example, a remuneration system in which the income of the more productive collective farmers is earned at the expense of the income of the less productive ones is suggestive of many intragroup tensions which are not explored even in theory; or a further pursuit of the theme of informal organization might have led to some fruitful inferences about the goal orientations of management. A second effect of the shortage of space is the absence of documentation and illustration of many interesting ideas, such as the statement that the glavk tacitly cooperates with the factory in many of its illegal actions, or that the class or group identification of a Soviet citizen is frequently determined in his youth. However, the documentation of factual statements is good and the author is careful with facts. The major exception, worth noting because it is important to the argument, is the labor draft status of women; contrary to the author's statement, women were included in the labor draft during the war and apparently still are.

The specific contribution of the book is that it culls out of the primary and secondary sources a number of sociologically relevant factors, classifies them in a convenient way, and brings them together in one place. Since the broad picture of the social relations in Soviet economic institutions had already been sketched out, the usefulness of the book would have been enhanced if the same space had been devoted to a more intensive study of fewer problems or fewer economic institutions.

JOSEPH S. BERLINER

Russian Research Center, Harvard University

Formulation and Economic Appraisal of Development Projects. Book I: *Major Course Lectures;* Book II: *Lectures on Special Problems.* Lectures at the Asian Centre on Agricultural and Allied Projects sponsored by the government of Pakistan and UN Technical Assistance Administration. (Lahore: Supt. Govt. Printing. 1951. Pp. xiv, 473; vii, 399. $3.00; $2.50.)

In late 1950 the government of Pakistan, jointly with the Food and Agriculture Organization, the International Bank and the United Nations, in-

cluding the Economic Commission for Asia and the Far East, sponsored a ten-weeks conference and workshop on economic development problems. The lectures now appear in print in virtually the form in which they were delivered. Consequently they display both the merits and weaknesses of oral presentation reduced to print; a freshness and informality of approach combined with an occasional tendency to be long-winded or not entirely clear. All the same the lectures make good reading and the lecturers deserve high praise for the success with which they carried off what must have been a difficult assignment.

Book I contains the "six major courses" of lectures as follows: "Development Projects as Part of National Development Programmes," by Hans W. Singer (U.N.); "Appraising Costs and Benefits of Development Projects," by J. Thomsen Lund (International Bank); "Methods of Economic Forecasting," by Mordecai Ezekiel (FAO); "Organization and Administration," by Marion Clawson (U. S. Dept. of Interior); "Financial Aspects of Economic Development" by Egbert De Vries (International Bank); and "Preparing the Final Prospectus and Proposal for a Development Project," by Mordecai Ezekiel and Kemal Suleyman Vaner (U. N.). Book II contains lectures on "Special Problems of Economic Development." Some of these are indeed special problems, *e.g.*, "Planning the Development of Asian Fishing Industries," or "Farm Management Aspects of Agricultural Developmental Projects," but a few are of more general interest, *e.g.*, "Health Problems of Development Projects." Few economists interested in economic development problems will not be benefited by reading Book II. But many will probably feel with the reviewer that most of the presentations in Book II are too technical to be assessed by an economist.

Of the lectures in Book I the reviewer believes that those by Singer and De Vries will be found of greatest interest to readers of this *Review*. Though a full discussion of their presentations cannot be given here, a few of the points that they particularly stress should be mentioned. Unfortunately this review will have to omit comment on the other monographs.

Singer lays particular emphasis on what he calls the principle of accumulation and the principle of interrelation. "Economic Development is a cumulative process. . . . The secret of development planning is to set in motion forces of cumulation" (p. 2). As the subsequent discussion shows, Singer means by this that there is no linear cause and effect relation between, for example, poverty and capital formation, basic industries and development, agricultural development and industrial development, demand for basic services and supply of basic services, etc. If the reviewer understands him correctly, Singer here is emphasizing that development or improvement in any one sector fosters and makes easier development in other sectors: in development and growth everything depends on everything else in an organic not a mechanical manner. This is the principle of accumulation or, perhaps better, the cumulative principle.

The principle of interrelation in developmental programing concerns the necessity of understanding such complexities as the relation between social-

overhead service projects and directly productive projects, between public and private projects, between dispersed development and concentrated development, between capital-extensive and capital-intensive projects, between consumption gains and further investment, etc. Any successful planned program of development will have to take hard decisions on all these points, in Singer's view, and it is well to recognize them from the start while avoiding making irrevocable commitments wholly on the one side or the other whenever possible.

A good part of Singer's lectures consists in spelling out what these two closely related principles mean in concrete terms. It is a highly enlightening discussion.

De Vries' lectures to some extent cover ground already made familiar by other U. N. publications. The reviewer, however, found particularly fresh and revealing his remarks on "Savings and Investment in S.E. Asia," "Seasonal Factors in Agricultural Financing" and "Summary of Development Problems of S.E. Asia." In all three sections De Vries' intimate and at times deeply sociological knowledge of S.E. Asia comes through strongly to give the reader a fuller understanding of the problems than he is ever likely to get from neat equations and tidy syllogisms.

This review has had to omit much that the reviewer would have liked to commend and comment on in the lectures of the other contributors. He hopes, however, that he has conveyed his conviction that these two volumes are generally excellent, and that he profited from them with real pleasure.

NORMAN S. BUCHANAN

University of California, Berkeley

Costa Rica: A Study in Economic Development. By STACY MAY, JUST FAALAND, ALBERT R. KOCH, HOWARD L. PARSONS and CLARENCE SENIOR. (New York: Twentieth Century Fund. Pp. xiv, 374. $3.00.)

The Twentieth Century Fund and the authors of this volume have put all students of problems of underdeveloped countries deeply in debt by this notable addition to a field of economic literature, so far more distinguished by good will and enthusiasm than by penetrating analysis.

The purpose of the book is twofold: first, to describe the economy of Costa Rica and its main development potentialities; and second, to discover the immediate contributions which technical assistance under Point Four—but presumably also technical assistance from international agencies—could make in accelerating economic development. Costa Rica was selected for this study presumably for two reasons: first, being a very small country, the major development priorities stand out more clearly and the number of important projects is more limited; and second, in a number of respects, Costa Rica presents rather more favorable opportunities for development and technical assistance than other underdeveloped countries.

The arrangement of the book is straightforward. The first two chapters (by Stacy May of the International Basic Economy Corporation) describe Point Four and the Costa Rican economy generally, and in relation to each other. Two chapters (by H. L. Parsons on loan from the U.S. Department of

Agriculture) deal with the agricultural sector. Three chapters (by Stacy May) deal with industries, utilities and commerce. Health and welfare are considered (by Clarence Senior of the Bureau of Applied Social Research of Columbia University). Foreign trade and exchange problems are discussed (by Just Faaland on loan from OEEC). The general analysis of the Costa Rican economy by sectors is concluded by two chapters on finance (by A. R. Koch on loan from the Federal Reserve Board). A concluding chapter draws together the results of the second analysis and presents conclusions and recommendations.

Contrary to many group reports of this kind, the report forms a consistent whole, and the staff of the Twentieth Century Fund, as well as the authors, are greatly to be commended for welding the individual contributions together. The reader of this volume has all the time the feeling that he is consistently, gently but firmly, directed towards the final conclusions. This ease of reading is assisted by the fact that the small size of the country makes a transition from general principles to specific projects rather easier than it is in larger countries. Assisted by the miniature scale of the problem, the analysis strikes a happy medium between a skeleton model and an economic almanac—that Scylla and Charybdis of reports of missions to underdeveloped countries.

One inevitable drawback of the book is that it was written under the immediate impression of the outbreak of hostilities in Korea. As a result, the authors seem much more concerned about the possibility of supply difficulties for Costa Rica than present hindsight would indicate.

Subject to this general acknowledgement of the high standard of the book, the following major criticisms may be made:

1. The study operates with a national income estimate of $180 per capita. This estimate is considerably in excess of the United Nations estimate ($125 per capita for 1949).[1] The difference between the two estimates may be attributed to the fact that the Twentieth Century Fund study has used official exchange rates. If the free market exchange rate had been used, a figure very close to the UN estimate would have been obtained. One wonders to what extent the optimism of this study on development prospects is related to what this reviewer believes to be an overestimate of the national income.

2. The study seems based throughout on the view that foreign assistance requirements are determined by the direct import requirements for equipment and material for development projects. This reviewer believes that this is a fallacy and that there is no necessary logical connection between the two.

3. The proposal to reduce food prices—*e.g.*, sugar prices—in order to release purchasing power for other products and create domestic markets, neglects the possibility that in the special conditions of an underdeveloped country the income elasticity of demand for food may be very high.

4. The stay of the members of the group in Costa Rica was very short (only six weeks for the group as a whole), and it is notable that frequently even on elementary and important matters, reliance is placed on random

[1] *National Income and Per Capita Incomes in Seventy Countries, 1949*. Statistical Office of the United Nations, October 1950.

interviews, the ideas of farmers, guesses, etc. (on page 130, even on fishermen's tales!). While fully recognizing the lack of information in underdeveloped countries, perhaps with a longer stay the group might have been able to undertake studies of its own on some of the problems involved.

5. From data given on page 114, it would appear that some $500,000 or so a year in foreign exchange is lost to the country through the smuggling out of gold. In a country of 800,000 people, this would seem a rather big problem and it is surprising that no reference and no recommendation is made to the possibility of utilizing this potential source of finance for economic development.

6. The report seems to operate too much with comparisons with the United States and ratios derived from U.S. data. A glaring example of this is to be found on page 134, where it is concluded that in Costa Rica "there seems to be even more opportunity in agriculture than in industry for productive improvement." This conclusion is derived from the fact that the ratio of per capita output in manufacturing to that of agriculture in Costa Rica is as high as 3:1, while in the United States it is only a little more than 2:1. This seems a very slender foundation on which to base such an important conclusion.

7. In its proposal to abolish "inefficient" small-scale retailing, the report seems to fail to take account of the fact that retailing is often an outlet for semi-unemployed producers and artisans. The report states on page 186: "Since many of the small retail establishments are at the same time producers of handicraft products, the growth of larger retail units might facilitate a larger scale of manufacturing, with its possible economies." To the reviewer, the link of retail trade and handicrafts seems to be a reason to be careful about increasing the scale of the unit in trade, rather than otherwise. It seems just as likely that handicraft production may be destroyed without being replaced by larger-scale manufacturing.

8. The report concludes from the data on changes in money supply 1940-49 that some savings must have taken place. This conclusion, however, seems only reached by neglecting the increase of population during the decade. On a per capita basis, there would appear to have been no increase in real money supply at all.

9. The report does not entirely escape the fallacy of scale. Thus, it is stated (p. 267) that "Costa Rica has up to now obtained only a small volume of financial aid." When the data are expressed on a per capita basis, however, it would appear that Costa Rica has received very appreciable financial aid from abroad.

10. The chapter on "Banking, Finance and Foreign Exchange" appears to be written in much more general and theoretical terms than the rest of the report, which goes directly to actual Costa Rican problems. This reviewer would moreover question the theory which permeates this chapter and is also embodied in the conclusions, that foreign investment may contribute to inflation. This seems a confusion of thought. A given degree of investment will be less inflationary the more it is financed from abroad. It is only when invest-

ment from abroad raises total investment by more than the influx of foreign capital that foreign investment can be said to be inflationary, and then only in comparison with the lower volume of investment which would have obtained in the absence of foreign investment.

11. The total cost and expected benefits of the projects suggested in the conclusions and recommendations are not worked out. In the absence of such figures, it is impossible to form an opinion whether the program suggested is well related to the resources likely to be available for economic development.

12. The report also raises some interesting problems of "welfare economics." On the one hand, the idyllic nature and charm of life on the Central Plateau of Costa Rica, with its eternal spring, are described; on the other hand, it is suggested that production should be shifted to other regions, particularly the Atlantic coastal area abandoned by the United Fruit Company because of the spread of the Panama disease. This seems to amount to a recommendation to sacrifice some of the "non-pecuniary advantages" of life on the Central Plateau for an increase in output.

Since this review has made a number of criticisms, it may be well to repeat that this is one of the best publications on economic development problems which has yet appeared. To offset the above-mentioned criticisms, this reviewer could give an equally long or longer list of intriguing points or of interesting analysis.

Statistics and Econometrics

Econometrics. By J. TINBERGEN. Translated from the Dutch by H. RIJKEN VAN OLST. (New York: Blakiston. 1951. Pp. xxi, 258. $4.50.)

Econometrics is an important method of economic research. Yet, because many economists have not had adequate training in econometrics they have not been competent to judge its results. This is partly attributable to the absence of a competent introduction to the basic elements of econometrics. Tinbergen's book is designed to fill this need as well as to acquaint the economist with some of the more important results of econometric research. Needless to say, Tinbergen is eminently qualified to undertake this task.

The book is divided into three parts: the matematical formulation of problems, the statistical treatment of problems, and the contributions of econometric research. Discussion of the mathematical formulation is centered upon the conception of a rigorous analytical model for a given economic problem. Economic theory is presented as a set of relations describing the logical structure of the economic mechanism. The main points of this section are Tinbergen's discussion of the function of mathematical economics, the

[2] The author is a member of the United Nations Secretariat, but the views expressed in this review are his private opinions and do not necessarily reflect the views of the United Nations Organization.

formalization of economic relationships, the nature and form of supply functions, some problems of macro-theory, and the stability of equilibrium. To this reviewer this section does not measure up to standards of clarity, conciseness and systematic coverage of argument we have come to expect from Tinbergen. For example, the description of the function of mathematical economics (p. 13) is insufficient for the reader interested in the power of this tool. And in the discussion of simple aggregation in macro-economic investigations (pp. 34-35) the dimension and meaning of the commodity in the macro-function derived from the micro-demand functions are not clear. However, it should be noted that the same section contains a series of valuable observations. Among them we find (pp. 15-16) Tinbergen's discussion of the relationship between statics and dynamics, in which he emphasizes the relative obscurity of static models. He points out that a sufficient specification of economic mechanisms requires some description of dynamic properties and that often the logical character of the relations in a static model are not clear unless the dynamic background of the theory has been specified. He notes that relevant differences between economc theories may be obscured by a strict equilibrium analysis.

Tinbergen's discussion about supply functions is highly suggestive. He distinguishes between two basic types of supply functions: quantity-setting and price-setting functions which reflect important differences in institutional arrangements. Two different logical interpretations can be attached to these two types of supply functions. They may be considered as two different explicit solutions of the same implicit supply function. Or we may consider the quantity-setting function as a definition of the boundary of the attainable set of values of the variables and the price-setting function as a description of the quantity-price behavior within the attainable set, determined by a given institutional context. In addition he indicates that supply-analysis should take account of the differences presented by an order-reaction and an inventory-reaction case. This last suggestion seems particularly relevant for macro-theory.

In his discussion of statistical problems Tinbergen has restricted himself to a short general description of a few basic elements. A short description of time series, their decomposition by various methods, and of simple and multiple correlation dominates this section. This part may be essentially conceived of as a reference list of statistical concepts basic for the econometric approach. Some of the newer developments are included, *e.g.*, the simultaneous equation approach. Nothing is mentioned about the important identification problem.

The most interesting part of the book is in the chapters on results and policy evaluations. Tinbergen's summary of results presents useful references to econometric studies on demand functions, cost functions, production-supply functions and various types of market elasticities. It also includes discussion of a relatively complex international trade model, applied to the situation in the Netherlands in recent years. The reader will find a careful study of this section highly suggestive and most rewarding.

The model is based on three behavior functions: (i) demand function for

the national product by the home market; (ii) demand function for the national product by the world market; and (iii) supply function of the national product in the form of a price-setting function. Here Tinbergen has once again demonstrated his renowned ability to construct a manageable model. He clearly reveals the devices needed to assure manageability of a model whose structure is more complex than most international balance of payments theories. These devices include linearizing the relations by selecting increments relative to a base period as endogenous variables, and choosing a suitable scale for some of the price and product variables. These steps are essential to scientific analysis. With the help of methods of statistical inference Tinbergen derives estimates as to the quantitative structure of his model. Such estimates are necessarily subject to some degree of uncertainty. This uncertainty would be reflected in any conclusions drawn from and policy evaluations based on the estimated quantitative structure. To limit this uncertainty Tinbergen considered five quantitative structures differing from his best estimate but still all of them lying within some feasible range. One of the interesting results is his estimate for the price-elasticity of exports and imports, an estimate which has been derived from an analytical framework larger than that usually encountered in such studies. In all six cases their sum is never below 2.3. From the model Tinbergen extracted some relevant information for an evaluation of the balance-of-payments problems. He found that an isolated price or wage policy is a highly inefficient instrument for achieving an equilibrium in international payments. Devaluation fares no better as an isolated instrument. His results indicate that the combination of devaluation and deflationary fiscal policy would be efficient and that the order of magnitudes of the required policy would be perfectly realistic. May the disciples of Balogh be converted!

Some quibbles and questions concerning this last part do not detract from its over-all excellence. Nonetheless, the reviewer wishes to express himself strongly on the character of Tinbergen's exposition. The book is designed for the general economist—not for fellow econometricians—but the general economist may well experience some difficulties in following the argument beginning on page 165. Tinbergen leaps over some of the steps he employed to combine relations. Such gaps and leaps will frustrate the general economist trying to follow the argument. A more explicit discussion would have been preferable on pedagogical grounds. Concerning the nature of the relations certain questions come to mind. Should the average propensity to import be treated as a kind of technical coefficient? Is there no evidence that this quantity is an endogenous variable, dependent on price and cost structure even for smaller countries? Does there not exist some evidence to the effect that the supply of products for exports depends (partially) on the level of home demand for the national product? Casual experience in the postwar period suggests this last hypothesis.

One of the last sections in the book contains an excellent discussion on the limitations of verbal treatment of problems in economic analysis. Tinbergen's comment on this point may be usefully considered by economists. The book as a whole enables the interested reader to obtain a useful conception of the

general nature of econometric research. But it seems doubtful whether he will derive any workable knowledge of econometric research methods which he did not have before. Such a textbook on econometrics has still to be written.

Economic Systems; Planning and Reform; Cooperation

The Dilemma of Democratic Socialism: Eduard Bernstein's Challenge to Marx. By PETER GAY. (New York: Columbia University Press. 1952. Pp. xvii, 334. $4.50.)

This intellectual and political biography of Eduard Bernstein, the leader of German "revisionist" socialism, is a competent and useful work. Unlike much current American literature dealing with one or another aspect of the socialist movement, its purpose is to understand the subject under investigation, not merely to grind a fashionable ideological axe.

The book is divided into three parts. The first deals with Bernstein's conversion to socialism in the 1870's, his exile from Germany by Bismarck's antisocialist laws and his years in Zurich and London, and his defection from Marxism after Engels' death in 1895. The second part discusses in detail the "revisionist" doctrine which Bernstein expounded and defended in the years just before and after his return to Germany in 1901. The third part resumes the story of Bernstein's career and its relation to the fortunes of German Social Democracy from 1901 until his death six weeks before Hitler came to power. In addition to published sources, Gay makes good use of the Bernstein Archives located in the International Institute for Social History at Amsterdam; and in finding his way through the intricacies of Marxian theory and German history, he has evidently profited from the guidance of Professor Franz Neumann of Columbia, under whose direction the study was undertaken. The style is clear and straightforward.

The material which Gay has assembled and digested allows us for the first time to see Bernstein in proper perspective and to judge his achievement fairly. He was a Fabian long before he ever went to England and indeed long before there were any Fabians, and his conversion to Marxism seems to have been more a matter of party loyalty and devotion to Engels than of genuine conviction. Seen in this light, his abandonment of Marxism after Engels' death seems to be not only natural but inevitable: he was merely giving expression to his own earlier and more deeply held convictions. That this took the form of "revising" rather than repudiating Marx was also inevitable under the circumstances: subjectively, Bernstein wanted to remain faithful to Engels, but much more important (this point seems to have escaped Gay), it was impossible to get anywhere in the German socialist movement in the late '90s unless one professed to be some sort of a Marxist. Bernstein was very far from being the *founder* of revisionism; it was already a strong tendency in the movement before he began to write about it, and by the early years of

the new century most of the German Social Democratic Party were practical if not theoretical revisionists. Bernstein's rôle was merely to formulate what a lot of people thought or felt, and his fame and popularity were in large part due to the fact that he provided the kind of theoretical justification and respectability they needed (also of course to the resounding applause of the bourgeois press—again a point overlooked by Gay). He was neither an original nor a powerful thinker, and his supporters and followers were an undistinguished and heterogeneous lot who created no lasting school of thought. After the Great Debate over revisionism had subsided (before 1910), Bernstein had nothing new to offer—his opposition to the war was a highly personal attitude, largely influenced by his Anglophilia—and during the Weimar period he had little influence and led an increasingly isolated existence.

The picture of Bernstein which emerges from Gay's careful review of his career is thus one of almost total failure. His theories enjoyed a momentary fame, not because of any particular merit but because of the special historical context in which they were first published. The practical politicians and trade union bosses who eventually came into control of the German socialist movement agreed with Bernstein—to the extent that they bothered to think about theoretical questions at all—but had no use for him in their inner counsels. And the content of Bernstein's message—the gradual conversion of the German middle classes to socialism, permitting a peaceful and legal transition to the new society—has been brutally belied by the whole course of German history during the twentieth century.

Gay, whose fondness for Bernstein is both obvious and understandable, tries hard to reach a more favorable verdict on Bernstein's career (especially in the last chapter), but the result only emphasizes the hopelessness of the effort. The truth is that, apart from (doubtless justified) encomiums to Bernstein's moral character, Gay is forced to recognize explicitly the meagerness of his achievement. "It must be said . . . that his doctrine made only a negligible *theoretical* contribution to Socialist thought" (p. 296). "The contribution of Revisionism to Socialist tactics was equally problematic" (p 297). ". . . the reformists gained power in the party quite independently of the Revisionist theorists" (p. 299). "It is certainly true that Bernstein was unfortunate in his supporters—not one of them understood his democratic Socialism sufficiently to develop it further" (p. 300).

It would, of course, be quite wrong to conclude that it was not worth while to write Bernstein's biography. On the contrary, he is a famous and controversial character who badly needs to be seen in proper proportions and perspective. It is Gay's merit that, despite his partiality for his subject, he gives us what we need for the purpose. At the same time, however, it must be said that he could have added greatly to the significance of his book if he had frankly faced the fact of Bernstein's failure and had inquired seriously into its implications. As it is, the book is good as an intellectual and political biography of Bernstein, but it never comes to grips with the crucially important problems implicit in its title.

Gay's handling of the economic theories in dispute between Marxists and

revisionists is on the whole adequate but uninspired. (This may sound like damning with faint praise; but in the present intellectual atmosphere in this country, it should be taken as—and is intended as—a compliment.) There is, however, one important exception: Gay's treatment of the capitalist breakdown issue seems to me to be deficient both as regards its meaning and its wider implications. At the very center of Bernstein's attack on Marxism is the alleged theory of capitalist breakdown which Bernstein simply takes for granted as being an assential part of Marx's doctrine. And yet the truth is that Marx had no such theory, as Gay himself in effect admits when he says that "Marx never presented a coherent picture of just how capitalism would come to an end" (p. 177). In spite of this implicit admission, Gay argues as though Bernstein had been quite justified in attributing a breakdown theory to Marx. Gay's reasoning seems to be that since Marx (undeniably) believed in the existence of *tendencies* to capitalist breakdown, it follows that he must be assumed to have believed in the eventual inevitability of capitalist breakdown. This is on a par with the well-known criticism of orthodox economists which maintains that because they assert the existence of tendencies to long-run equilibrium, they must also believe in the reality of long-run equilibrium. It is a time-honored method of criticism, and it leads to easy verbal victories —but also to quite irrelevant conclusions. Gay's failure to see this vitiates his whole discussion of the breakdown controversy (pp. 176-90). This is too bad, since the problems involved in this controversy are among the most difficult and important in the whole field of political economy and in a very real sense dominated the debates between the revisionists and the orthodox Marxists.
